This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at http://books.google.com/

SPECIAL OPPORTUNITY

To Secure a Copy of the

Textbook of Aero Engines

By E. H. SHERBONDY and G. DOUGLAS WARDROP

Together With One Year's Subscription to

AERIAL AGE WEEKLY

The Leading Technical and Trade Aeronautic Publication in America

The Textbook of Aero Engines has been prepared for the purpose of having in one volume the complete information concerning all modern types of aero engines and an up-to-the minute discussion of the principles of aero engine design and construction, so that the reader may be able to undertake comparative research without recourse to a formidable list of volumes and publications, which in any event could only supply him with more or less obsolete information.

AERIAL AGE WEEKLY discusses and describes all current developments in the aero engine field, so that with the Textbook and consecutive copies of AERIAL AGE the subscriber will possess a complete encyclopedia on the subject.

To AERIAL AGE WEEKLY
280 Madison Ave., New York

Please send me a copy of the Textbook of Aero Engines (regular price $10.00), and enter my name on your subscription list for one year (regular price $4.00). I desire to take advantage of securing both at the special price of $10.00, and am enclosing my check for that amount herewith.

Farman

SPEED-RANGE

The greatest problem in Aviation today is *slow flying.* Almost all airplanes are *fast* enough. Almost none are *slow enough.*

Speed-Range is the difference between the lowest flying speed and the highest flying speed of any particular airplane. If the lowest speed should be 40 m.p.h. and the highest speed 80 m.p.h. the *Speed-Range* of that airplane would be $\frac{80}{40}$ or 2.

Evidently, the higher the *Speed-Range,* the safer and more efficient the airplane.

The FARMAN two-seater is the *slowest flying Airplane in the World,* and it also has a high speed of almost 90 miles per hour.

When you ride in the Farman you enjoy the most wonderful sense of comfort and security it is possible to realize in the air, because your Farman possesses *Speed-Range,* the most important factor in Aviation, to a superlative degree.

Two-seater Touring and Sport Model $4850.00.

VOL. XV NEW YORK, MARCH 27, 1922 No. 3

Urges National Airway System for the United States

BRIGADIER-GENERAL WILLIAM MITCHELL, assistant chief of the Air Service, recently returned from Europe, where he made a very comprehensive survey of aerial activities. In a statement issued at the offices of the Aeronautical Chamber of Commerce he urged the establishment of a system of national airways in the United States. He said, in part:

"Europe is making great strides in the development of aviation, but in its actual application, as illustrated by the bombing manoeuvers last summer, we are in the lead. What the United States needs is an organized system of airways, Federal laws and some form of tangible encouragement for its civilian operators. Some 12 or 15 aircraft lines are in operation in England, France, Holland, Belgium and Italy. The air port of London (Croydon) and Paris (Le Bourget) are well organized and sÿstematically conducted, with customs houses, hotels and means of communication with the city. People in Europe are patronizing the air lines as a utility. During the month of February about 1,400 passengers were cleared at the Paris Air Port. The French are running the longest lines—Paris to Bucharest, with an extension to Constantinople. In all the larger European nations aviation is being developed with the idea that it is the first line of defense, and subsidies of 50 per cent. or so on the original cost and the cost of operation are in effect for privately owned aircraft.

"There is no visible aviation in Germany, but they are doing great things there. The gliding flights are evolving types with motors of only 5 h.p., which means a very cheap ship.

"The French intend and the Germans expect to fly the Atlantic. Airships have not been scrapped, but are sure to be the long distance carriers. The German-Spanish-Argentine Zeppelin line between Seville and Buenos Aires is going through."

General Mitchell flew in every country visited, personally testing out some fifteen new types of aircraft, again demonstrating that the affairs of the Army Air Service are in good hands, for General Patrick and General Mitchell are both practical and efficient aeronautic enthusiasts.

Modern Forest Fire Fighting

WE have editorially urged on more than one occasion the greater utilization of aircraft for forest fire patrol, and we are glad to have the following comment from Paul G. Redington, district forester at San Francisco:

"Special flights over and around large fires to get a comprehensive view of the situation are of inestimable value. Very often we have fires in such rough and inaccessible country that it would take a day or even more for the man in charge to get around them, size up the situation and determine his plan of attack. Of course in the meantime the situation might entirely change, and he would be little better off than when he started. If, however, he makes use of a plane he can, in an hour or less, get an accurate picture of the fire, and can immediately so dispose of his forces as to attack it most effectively. Such flights should of course be made with the man in charge of the fire or an experienced fire fighter as observer, since a great deal will depend upon his personal judgment. If desired, an emergency radio station can be established on the fire line and direct communication may be had from the plane to the ground. All pilots are radio operators, so that if the forest officer who is flying as observer is not qualified in this respect he can write out the messages and hand them to the pilot for sending. However, even if no radio is used there is very little delay in the dispatching of the information gained, since a plane traveling at ninety miles an hour will return to a landing field in a few minutes, and the observer can then report by phone or in person."

A New Gas for Airships

CURRENIUM is the name given a new gas for airships, which has been developed by Dr. Edward Curran, head of the research department of the International Transportation and Manufacturing Company, of Los Angeles, which controls the formula and all rights in the product. It is the result of several years' work by Dr. Curran, who is a chemist, and who produced the gas successfully in 1918. The company owning the formula is preparing to engage in the manufacture of the gas, by an electrolytic process at a cost, it is estimated, about $100.00 per thousand cubic feet less than it costs to produce helium.

We expect to present to our readers next week more comprehensive information concerning this important new development in the lighter-than-air field.

THE NEWS OF THE WEEK

To Fly from Lisbon to Rio

Lisbon — Three Portuguese cruisers left March 25 to station themselves at different points in the Atlantic Ocean to act as a convoy for two Portuguese officers who will attempt to fly a hydroaeroplane from Lisbon to Rio Janeiro.

The date of the start of the flight has not been definitely fixed, but the aviators hope with favorable weather conditions they will be able to make the trans-Atlantic passage of more than 4,000 miles in sixty hours. The machine they will use will develop 360 horsepower and is expected to attain a speed of 80 miles an hour.

The route of the aviators will be from Lisbon to the Canary Islands, thence to the Cape Verde Islands, from there to Fernando Noranha, a short distance northeast of Pernambuco, and then southward to Rio.

Pescara Helicopter Ascends

Paris — At a private trial before a number of French flight experts and airmen Marquis Pateras Pescara on March 22 succeeded in raising himself with his helicopter to a height of six feet from the ground. The trial was made inside a big airship shed at Issy les Moulineaux and was considered more difficult than if it had been made in the open air, as the revolution of the lifting wings caused an enormous back pressure from the sides of the building. The inventor further handicapped himself by agreeing to rise and land within a circle ten meters in diameter.

At the first attempt the helicopter, which is the same as that tested at Barcelona last Summer, rose fifty centimeters. It was found that the engine had got too hot. When the air in the building was cooled a second attempt was made, and the marquis rose to a height between three and five feet several times in succession, always landing within the prescribed circle, although the helicopter showed a tendency to tilt backward. At the third attempt it rose vertically to a height of two meters and landed without the least shock. The only fault found by the experts was the tendency of the machine to tilt backward on landing; and this, it was explained, was more the fault of the inventor, who is not an expert pilot, than of his machine.

The Marquis is completely satisfied with his achievement and intends to begin the construction of a second machine which, as well as rising vertically, will be capable of lateral flight.

Flying Club Names Field for Albert Bond Lambert

The Flying Club of St. Louis at a dinner meeting recently voted to name its field at Bridgeton, Mo., in St. Louis County the Albert Bond Lambert Field in honor of Albert Bond Lambert, president of the Lambert Pharmacal Company and a St. Louis airman of national prominence.

Judge Daniel G. Taylor, vice president of the Missouri Aeronautical Society, an organization with which Lambert has long been affiliated, made the principal address. He mentioned Lambert's conspicuous service for aeronautics in Missouri and spoke briefly of the record which the Flying Club has made.

A number of flyers from Scott Field attended. Among the speakers were Maj. A. E. Stocker, commandant of the aerial reserves in St. Louis. About seventy-five attended the meeting.

The program was concluded with the official air service moving pictures of the bombing tests carried out in Hampton Roads last summer.

British Airship Is Offered to Us

London.—A proposal for the participation of the United States Government in the purchase of one of the British airships was made March 22 by Major G. H. Scott, pilot of the R-34 on her two successful transatlantic flights, to Commander White, one of the Naval Attaches here. Commander White has transmitted the suggestion to Washington.

Major Scott expressed his willingness, The New York Times correspondent understands, to negotiate the taking over of the airship from Great Britain if he receives American backing to raise and train a crew here and navigate the ship himself across the Atlantic. He believed he could interest British financiers in the plan, but it would be necessary to ascertain the attitude the United States authorities would assume toward the project before entering upon financial details.

The British Government has at present five airships, the R-33, R-36, R-37, R-80 and L-71.

Of these the R-36 is fitted up as a passenger ship with sleeping and dining equipment, while the L-71, which was taken over from the Germans, needs a new gas bag. They are all now for sale without restriction, after the British Government had come to the conclusion that it could not afford to run airships as a part of its military equipment.

Navy Exhibits Model of Pulitzer Winner

Washington—A model of the Curtiss-Navy racer, winner of the Pulitzer Trophy race at Omaha on Nov. 3 of last year, has just been presented to the Navy Department.

The plane is a joint production of the Curtiss Company and the Navy Department, built for the navy. This speedy plane is powered by a new twin six Curtiss engine.

In the Pulitzer race the plane was piloted by Bert Acosta for the Curtiss Company. Acosta covered the 150 mile course in 52 minutes 9 3-5 seconds, or at an average speed of 176 miles per hour.

Acosta was the first to get away in the race, and at no point lost his lead. Naval flying experts were greatly impressed with the performance of the Curtiss-Navy racer, which was loaned by the Navy Department to the Curtiss Company to be flown in the Pulitzer race.

Amundsen Tests Plane

Capt. Roald Amundsen, the arctic explorer, who left Mineola Field in a Larsen monoplane shortly after noon March 30, reached Bolling Field at 2:55 o'clock the same day. Some rather severe weather was encountered on the trip from New York to Washington. For about 150 miles after the plane left Philadelphia snow and sleet with rains were encountered, the weather was quite thick and it was necessary for the pilot to fly the plane just over the housetops in the trip. Near Baltimore, however, the weather cleared up and the trip was made with comparative quickness on to Washington.

Amundsen will take this machine into the Arctic when he starts his long drift across the polar regions next summer. John M. Larsen, owner of the model, has presented the plane to Amundsen and the explorer has expressed great satisfaction at obtaining a machine which has created such a marvelous endurance record.

Mapping Air Route from U. S. to Canal Zone

The War Department is working out an air route from the United States to the Panama Canal Zone by way of Havana. The plan is part of the defense plans of the zone, which include the establishment of an elaborate air base there.

The plan is to establish a base by arrangement with Cuba at Havana, from which point it is believed the airmen could hop off to British Honduras and thence to Costa Rica, making the Canal Zone on the last lap. This would obviate the necessity of arranging for a landing base in Mexico.

Spokane News

Spokane, Wash.—The Litzenherger Brothers, Endicott wheat farmers, landed in Spokane by aeroplane recently to secure a competent woman cook for their farm operations. They had planned to take the successful applicant back with them via the air lanes, but the idea of daring the high places did not appeal to the material available and more prosaic methods of transportation were insisted on.

Fourth Aviators' Ball

Plans for the fourth annual aviators' ball, to be held at the Hotel Astor on Monday evening, April 24, are rapidly swing-

COMING AERONAUTICAL EVENTS

AMERICAN

Apr. 30.—Spring Show and Opening Meet, Curtiss Field, Mineola, L. I.

May —National Balloon Race.

Sept. 4.—(*about*) Detroit Aerial Water Derby, Detroit. (Curtiss Marine Flying Trophy Competition.)

Sept. 15.—(*about*) Detroit Aerial Derby, Detroit. (Pulitzer Trophy Race.)

Sept. 30.—First Annual Interservice Championship Meet. (In preparation.)

FOREIGN

Aug. 1.—(*about*) Coupe Jacques Schneider. (Seaplane speed race.) Italy, probably Venice.

Aug. 6.—Gordon Bennett Balloon Race, Geneva, Switzerland.

Oct. 1.—Coupe Henri Deutsch de la Meurthe. (Aeroplane speed race.) France. American elimination trials, if required, to be held about Aug. 15, at Mitchel Field, L. I.

Digitized by Google

ing into shape, and give promise of making the ball, as it always has been, a brilliant close to the Winter's social season. The patronesses and the committee chairmen include Mrs. Charles Dana Gibson, head of the patroness committee; Barbara Brokaw, of the junior committee; Emily Chauncey, of the entertainment committee; J. Philip Roosevelt, of the Army aviators' committee; H. Rogers Benjamin, of the Naval aviators' committee, and Emerson MacMillin, treasurer of the hall.

Other patronesses are Mrs. Laurence La T. Briggs, Mrs. R. Drace White, Mrs. Edward Breitung, Mrs. Rogers Benjamin, Mrs. Henry S. Zuckerman, Mrs. Donn Barber, Mrs. Charles T. Barney, Mrs. Gutzon Borglum, Mrs. Marie Bernard, Mrs. Elihu Chauncey, Mrs. John Daniel, Mrs. Charles de Rham, Mrs. Nelson Doubleday, Mrs. Henry H. Flagler, Mrs. Lyttleton Fox, Mrs. R. Horace Gallatin, Mrs. Henry F. Godfrey, Mrs. Enrico Caruso, Mrs. Jay Gould, Mrs. Emanuel Gurlie, Mrs. E. M. House, Mrs. Otto Kahn, Mrs. Goodhue Livingston, Mrs. John Lee, Mrs. John Purroy Mitchel, Mrs. John B. Marsh, Mrs. J. P. Meuer, Mrs. Lewis Gouverneur Morris, Mrs. James Lowell Putnam, Mrs. George B. Post, Mrs. H. Rivington Pyne, Mrs. Monroe D. Robinson, Mrs. Theodore Roosevelt, Jr.; Mrs. Phillip Rhinelander, 2nd; Mrs. Malcolm Sloane, Mrs. Morton L. Schwartz, Mrs. George B. St. George, Mrs. Samuel Wagstaff and Mrs. Henry Rogers Winthrop.

Among those who will serve on the junior committee are Barbara Brokaw, Elizabeth Andrade, Ellin Mackay, Jeanne Reynal, Helen Meurer, Alice Beadleston, Louise Wilson, Marion de Rham, Gabrielle Gourd, Margherita De Vecchi and Mrs. Thomas Finletter.

Plan Air Service to Atlantic City

Regular daily air service between the Ritz-Carlton Hotels in New York and Atlantic City will be inaugurated in a few days. According to C. N. Reinhardt, who is in charge of the arrangements, passengers desiring to travel by air from New York to Atlantic City will have the choice of land and water routes. Five and ten passenger planes will be used. Eventually the regular service may be extended to Washington, Philadelphia and other cities. Bookings already have been made at the Ritz-Carlton here.

A year ago the rate for an air trip to Atlantic City was $100, but the new rate probably will be about $35. The machines will be chartered from established companies, including the American Airways Company, of which Mr. Reinhardt is a Director. This company, he says, has available ten five-passenger H-S-2-L planes of the navy bomber type, and soon will have ready six more machines, including two Curtiss flying boats of the two-passenger type. It is also planned to acquire a twelve-passenger flying boat from the American Transoceanic Company, and fast Leoning machines and probably some Fokker monoplanes. "The flying boats," said Mr. Reinhardt, "will start from Eighty-third Street and the Hudson River. If the Fokkers are employed, they will take on their passengers at Garden City, L. I. Passengers booked at the Ritz-Carlton Hotel will be transported by motor car to the points of departure, where they will be placed aboard the flight machines."

Mr. Reinhardt said that the reduction in the rate for air transportation had been made possible by the low price at which the Navy Department is selling its surplus stock of air machines. ,"The larger flying boats of the ten-passenger size, which cost the Government in the neighborhood of $30,000," he said, "can be bought for $6,120. The two-passenger flying boats, which were acquired by the Government at prices up to $13,000, can be obtained for as little as $2,000.

"I have been informed that the attractive prices at which these flying machines are offered to the public by the Government have created a great demand for aeroplanes," he added, "and that more than a dozen individuals within the last three weeks have bought planes from the big stock awaiting disposal at the Philadelphia Navy Yard. Most of these machines are brand new."

St. Louis Club Banquet

The Flying Club of St. Louis held their Monthly Banquet at the Hotel Claridge, March 13, and a very pleasant evening was enjoyed by all those present.

About 250 members including friends and also a number of officers and enlisted men were present from Scott field. Several short talks were made by the officers from Scott field, the Flying Club also renamed their flying field which was opened last December to be named Lambert field in honor of Major Lambert of St. Louis who has been a big figure in aviation for a number of years.

The club is starting a drive on for new members and it is the hope of the club to increase its membership by 100 per cent.

Moving pictures were shown of the Bombing tests that took place last June.

The Flying Club's new field at Bridgton, Mo., will be the scene of much flying this summer, and a number of interesting events will take place there.

Witchita Falls Meet

An aviation meet and carnival is being planned for Wichita Falls by the local American Legion Post, and will be held April 29-30. It is expected that thirty planes will participate. Government planes from Fort Sill will co-operate.

AERONAUTICS IN CONGRESS

The following memorandum concerning the progress of aeronautic matters in Congress has been prepared by the Aeronautical Chamber of Commerce.

Feb. 8. *Senate*—Mr. Jones of Washington introduces S. 3076, a bill to establish a bureau of Aeronautics in the Department of Commerce for the purpose of making it unfinished business.

Feb. 11. *Senate*—Appropriation for the National Advisory Committee for Aeronautics struck out of Executive and Independent executive bureau bill (H. R. 9981) by the Senate because of the pending bill S. 3076 to create a bureau of aeronautics in the Department of Commerce. Which brought up question of the need of the National Advisory Committee for Aeronautics.

Feb. 13. *Senate*—S. 3076, a bill to create a bureau of civil aviation in the Department of Commerce discussed in the Senate.

Feb. 14. *Senate*—S. 3076 passed the Senate 34 yeas and 16 nays.

Feb. 15. *House*—Message from the Senate that it had passed S. 3076 and wished concurrence of the House.

Feb. 20. *Senate*—Correspondence between Secretary Hoover and the Attorney General regarding trade associations inserted in the record.

Feb. 28. *House*—Mr. Hicks: a bill (H. R. 10617) to authorize the conversion of battle cruisers into aeroplane carriers; to the Committee on Naval Affairs.

March 1. *House*—Petition 4368. By Mr. Frothingham: Resolution passed by the Quincy (Mass) Chamber of Commerce, praying for the converison of the cruiser Lexington to an aircraft carrier; to the Committee on Naval Affairs.

Petition 4380. Petition of the Commercial Aircraft Association of Southern California, Los Angeles, California, indorsing and urging support of the Hicks bill (H. R. 2815) a bill to create a bureau of civil aviation in the Department of Commerce; to the Committee on Interstate and Foreign Commerce.

March 3. *Senate*—Mr. Lodge presented petitions of 7,829 citizens of the city of Quincy, Mass., praying that the battle cruiser Lexingon, now under construction at the Fore River yard be converted into one of the two aeroplane carriers authorized unduer the naval treaty, which were referred to the Committee on Naval Affairs.

House—Second Deficiency Appropriation Bill. An amendment to provide $150,000 for helium experimentation and production cost.

Mr. Hicks: a bill (H. R. 10712) to authorize the conversion of battle cruisers into aeroplane carriers; to the Committee on Naval Affairs.

Mr. Kelly of Penn.: a bill (H. R. 10717) to encourage commercial aviation and authorizing the Postmaster General to construct planes for air mail service; to the Committee on Post Offices and Post Roads.

March 6. *House*—Mr. Hicks: a bill (H. R. 10742) to authorize the conversion of battle cruisers into aeroplane carriers; to the Committee on Naval Affairs.

March 9. *House*—Conference report on H. R. 998 (Independent Office Appropriations Bill) advises Senate to recede from its disagreement to Amendment No. 26. This amendment carried an appropriation of $200,000 for the National Advisory Committee for Aeronautics and $10,000 for the construction of an additional laboratory building. This amendment has been agreed to by the House.

March 14. *House*—In submitting the Army Appropriation Bill H. R. 10871 the Committee cut the Appropriation of the Air Service to about $12,000,000. The Director of the Budget allowed $15,000,000. Of the $12,000,000, $6,000,000 is allowed for the purchase of planes, $400,000 for lighter than air and $400,000 for helium experimentation and production.

Later in the discussion Mr. Fitzgerald in speaking on this bill urges the need of more money for experimentation.

March 16. *Senate*—In discussing the Four Power Treaty, Mr. Reed introduces into the record the number of aircraft carriers of Great Britain, Japan and the United States with their speed, their armament and aircraft carrying capacity. United States has one; Great Britain 7; Japan 1.

March 17. *House*—A document by Rev. M. D. Shutter of Minneapolis on "The Army of the United States as a Constructive Force" was introduced into the record. In this document, he speaks of the extensive savings in timber by the use of the Forest Fire Patrol.

March 18. *Senate*—Appropriation of $1.900,000 allotted for the air mail service by the Senate.

The AIRCRAFT TRADE REVIEW

Aerial Service Between San Francisco and Los Angeles Starts Daily Operation

With the delivery of two Aeromarinc Navy HS flying boats to the Western Airway Company of San Francisco, began a new era in aerial transportation on the Pacific Coast. Announcement of this new aerial scrvice was made today by C. F. Redden, President of the Aeromarine Engineering and Sales Company who have recently sold these two boats to the Western Airway Company.

A regular passenger and freight air service between San Francisco and Los Angeles is already in daily operation. One of these flying boats leaves San Francisco at 8:30 in the morning and another leaves Los Angeles at thc same time. The fare for the total distance is $50 per passenger.

O. L. Gagg, Pacific Coast Representative for the Aeromarine Company, stated recently that with the first of these Aeromarine Navy boats already in operation it would not be long before a large fleet of these. same type boats would be winging their way between California cities.

With the opening of the flying season, sales of the Aeromarine Navy HS flying boats are becoming frequent. The Easter Airways, Inc., of Baltimore, Maryland, who recently purchased two additional Aeromarine Navy HS flying boats have started one of these boats on a long commercial flight under the direct charge of the President, Mr. P. E. Easter.

The first boat is now in Florida enroute to New Orleans.

"Wherever there is a large body of water in the United States, Aeromarine boats have flown," said Mr. Redden. "Their distinctive white wings and hull have become a familiar sight to thousands of people and are establishing in the minds of the general public the fact that aerial transportation properly conducted is absolutely safe. We ae more than gratified to see the interest taken on the Pacific Coast in Aeromarine boats, and expect as rapid devlopments out there as we have seen in the East and Florida."

Loening in New Building

The Loening Aeronautical Engineering Corporation is now established in its new and specially equipped factory at Thirty-first Street and East Rivcr, New York City.

National Aircraft Underwriters Moves

The offices of the National Aircraft Underwriters' Association, formerly at 15 Park Row, New York City, are now at 120 West 42d St.

Hungesser Uses Farman

Capt. Nungesser, next to Fonk, the greatest of French Aces of the World War, with a total of over 70 official victories, has entered his order for a "Farman" two seater Touring Plane to be delivered to him on April 13th. Capt. Nungesser expects to make an aerial tour of Europe in the interests of commercial aviation.

Aeromarine News

New York, March 24, 1922—The disappearance and loss of a passenger carrying seaplane between Florida and Bimini is attributed to the lack of a Fedcral law enforcing the inspection of aircraft, according to Charles F. Redden, president of Aeromarine Airways, of New York and Key West, which to-day ordered to sea five flying boats and their surface acroplane mother ship to aid in the search for the missing craft. Mr. Redden sent the following telegram to the Chairman of the House Committee on Interstate and Foreign Commerce, which has now before it the Wadsworth Bill, providing for the regulation of aerial traffic:

"The seaplane which is reported missing off the Florida coast, with five passengers aboard, has attracted wide comment illustrating the peril of flight. This seaplane does not belong to the Aeromarine Airways fleet and should not be identified with our operations between Key West and Havana. Flying is just as safe to-day as travelling by rail, when rigid inspection of equipment is provided, eithcr by private organization or by public authority. The fact that we have transported thousands of passengers from the mainland to Cuba without injury or loss of life, is explained by rigorous requirements and extensive facilities. These, however, are the exception in much of the general flying that is now going on. Aircraft four and five years old, never properly overhauled or maintained, operate over territory which, under conditions, invite disaster. When a mishap occurs, legitimate aviation gets the blame. Such accidents will multiply with increasing loss of life and to the consequent detriment to aerial transportation, unless Congress passes, without delay, the Wadsworth Bill providing for inspection of machines and licensing of pilots and establishing a Bureau of Commercial Aeronautics in the Department of Commerce."

LIFE INSURANCE AND AERONAUTICS

By R. R. BLYTHE

THE Commercial Aircraft Companies have in the past often brought up the question about the validity of the life insurance policies applying to the passengers in case of death caused by the participation in aerial flight.

A life insurance policy is a contract issued by a company or corporation to a person to indemnify the beneficiary or beneficiaries in case of death.

Since a life insurance policy is a life contract between the company and the assured, it is important that the company (and therefor directly or indirectly the policy-holders) know whether the applicant is engaged in an occupation or profession which is extra hazardous or whether the physical conditions of the applicant are normal, in order that the ordinary span of life may be expected.

If this information is correctly given and accepted by the company, in most cases the policy is incontestable for any cause whatsoever after having been in force one or two years, depending on the company; with the exception of thc fraternal orders, who do not have any uniform rules in this connection. To quote the actual wording from one of these life insurance contracts, it states that "there are no restrictions under this policy while in full force of travel, residence, occupation or military or naval service." This would also include aeroplane flights as passenger or otherwise.

In the New York *Times,* Sunday, March 26, the following item appeared: "The Larabee Flour Mills Corporation will collect $200,000 as the result of the death of August Bulte, who perished in the seaplane Miss Miami."

Three officials of the same corporation in November, 1919, applied for life insurance of $600,000, the policies payable to the corporation. The applications for insurance of $200,000 each were from Frank Larabee, Fred D. Larabee and August Bulte. Policies were issued to Mr. Bulte and Fred Larabee, but the application of Frank Larabee was held up.

The next March Fred Larabee died and his company was paid $200,000. He had paid one premium.

Frank Larabee reapplied for insurance in September, 1920, and obtained a $100,000 policy. He died in June, 1921, after paying one premium, and $100,000 was paid to his company.

The policy issued on the life of August Bulte in November, 1919, has drawn three premiums to date. Through corporation insurance of its officials the Larabee mills will have collected one-half million dollars in two years. The total premiums paid was about $17,000.

It is usual in most life insurance companies to issue what is known as a "double indemnity" coverage at the approximate rate of $1.00 extra premium for each $1,000 in the amount of the policy. This double indemnity stipulates that in case of accidental death of the person therein insured double the amount of the policy shall be paid to the beneficiary or beneficiaries.

There is a clause in reference to this article which reads somewhat as follows: "The double indemnity feature of this policy does not cover during military or naval service of any kind in time of war or by engaging as a passenger or otherwise in submarine or acronautic expedition."

It may be, therefore, stated that in most cases where life insurance has been issued without question and is in force one or two years, as per stipulated incontestable period in the contract, that any claim arising from death suffered from participating in aeronautics is not contestable by the life insurance companies.

THE PROGRESS OF RESEARCH

By Brig. Gen. R. K. BAGNALL-WILD, C. M. G., C. B. E., F. R. A. E. S.

Director of Research in the British Air Ministry

(Concluded from page 79).

Navigation

The most difficult of all problems in connection with "Navigation" is the provision of means in foggy or misty weather to enable an aircraft to locate the aerodrome for which it is bound and to make a successful landing to it. Unquestionably it is this difficulty which causes pilots on long routes to prefer to fly under, rather than over, clouds. Professor Jones, in a paper read not long since before the Royal Aeronautical Society, gave many reasons why it would be better for such flights to be made above the cloud layer, but ample experience before then and since has shown that it is no use to expect pilots to do this until their minds are reassured as to the adequacy and reliability of the ground organization enabling them to make safe landings through fog.

As one of the Committees of the main Aeronautical Research Committee, Professor Lindermann suggested that the best means of landing in a fog might well prove to be the provision by the aerodrome so afflicted of two pairs of small kite balloons floating above the cloud layer, the first pair being at such an altitude as would enable a gliding machine, which passed between them, also to glide between the second, and lower, pair, and after an equal interval of time to land on the aerodrome.

In the case of thin fogs or ordinary mists it may be that the specially bright red ground-flares which are now being tried will suffice. In heavy fogs there is always the possibility, given the right ground organization, of detecting the position of an aeroplane by sound and of signalling to it by wireless when to glide down and in what direction. This has been done successfully at Croydon.

Suggestions have been made to get rid of the fog either by mechanical means of pumping, or alternatively by electrical discharges, or even by burning vast quantities of coal or other fuel in order to warm the air above the saturation point; these three methods could easily he tried on a small scale and would doubtless work; when, however, they are figured out for an aerodrome of normal size the cost of their introduction is found to be prohibitive.

When in 1912 use was made of the precessional movement of a gyrostat to measure the velocity of roll on one of His Majesty's ships, it was not contemplated that by far the most successful application of the apparatus would prove to be for air travel; it is known as the gyro turning indicator, and ample experience has shown that it is more sensitive and much more rapid in its indications than any other method that has been trip for indicating the turns of an aeroplane. Unlike the use of a constant azimuth gyro, this apparatus does not need to be delicately balanced as regards the position of its center of gravity, and is therefore remarkably fool-proof. Aeroplanes flying in a fog frequently get into turns without knowing it, and when they do so, the magnetic compass, particularly when of an old pattern, is pretty sure to indicate a turn in the wrong direction, and so thoroughly mislead the pilot.

Modern compasses are much less affected than were their predecessors by the yawing oscillations of an aeroplane or even by moderately rapid turns off North, and this is due in the first instance to the work of Keith Lucas and Lindemann when at th Royal Aircraft Establishment, and later by the work of Dr. Bennett of Emmanuel College, Cambridge, and the late Lieut.-Commander Colin Campbell of the Admiralty Compass Observatory. The Farnborough work showed the advantage gained by a long period, whilst the later inventors pointed out the great advantage of damping the oscillations of the magnetic needles even to the point of aperiodicity.

It is a natural speculation as to what is likely to be the amount of deviation error in the magnetic compass when machines are built entirely of steel. Such tests as have already been made are, however, reassuring in this respect. It seems that the deviation error in any machine is largely dependent on the proximity of the engine, and that this effect predominates whether the framework is construeted of wood or of steel.

As regards navigation, either when flying over the sea out of sight of land, or when flying at any time above clouds, the necessary instruments to enable the position to be determined by the methods of nautical astronomy are now availahle. They have become sufficiently developed to enable the position to be obtained with a probable error not over ten miles. This is as high a standard of accuracy as is necessary for ordinary air work: it enables a check to be made on the Dead Reckoning course, and upon any determinations of positions derived from wireless methods.

The study of Directional Wireless is being steadily pressed forward. A particularly promising form of it is the rotating wireless beacon; this method offers the very considerable bait of freedom from the troublesome quadrantal error, but it, like other wireless methods, depends for its ultimate accuracy on a careful study of the conditions which determine the nature of the path followed by the waves.

Machines

The question of stability is being continuously studied, and I hope in the future that it will prove possible so to organize the work as to give more time to this important subject. If possible, one of the National Physical Laboratory wind channels should be allocated entirely to this work.

Stability may be either inherent or automatic. Automatic stability is attained through the operation of some more or less complicated auxiliary mechanism, whilst inherent stability is stability due directly to the nature of the design of the aerodynamic surfaces, the disposition of weights, etc. If inherent stability can be attained there will be small need for automatic stability. At present the problem of longitudinal stability is to a large extent solved, but that of lateral stability still requires a great deal of work to be done upon it. Much has also to be done on the measurement of pressure distribution over wing surfaces; I hope that in the future it will be possible to give more time to this subject.

Not a little public attention has been drawn to the interesting arrangement of slotted wings proposed by Mr. Handley Page. A large Handley Page monoplane wing with a single long slot is now at Farnborough awaiting test. This wing also has short slots in front of each aileron. Two other new Handley Page designs are also in hand. The results will be followed with great interest. The earlier trials have shown very remarkable results. A D.H.9 aeroplane, fitted with a Puma engine, was found when equipped with a Handley Page wing to have both greater aerodynamic efficiency and greater climbing capacity than when fitted with the standard wing. The climbing slope in the one case was 1 in 7.2, and in the other 1 in 10.4. This is an important consideration when clearing obstacles around an aerodrome. Moreover, for getting off and on to decks, it was found that the launching run witb the Handley Page wing was less than half that necessary with the standard wing under similar conditions. Public attention has also been drawn to the "Alula" wing, and careful tests have been made of models in the wind channel; these have not so far demonstrated that a wing made in this fashion should be exceptionally good, but it is conceivable that the scale effect between a model and a full size may be unusual in a wing of this shape. The point is being looked into.

As regards propellers there is no doubt, as has been pointed out by my predecessor, that a complete metal propeller would he a great boon. I would even go so far as to say that for all Service aeroplanes in the East tbey ar essential, even at the cost of a greater propeller weight. For sizes of over 450 hp. there is reason to hope that the increase in weight will not exceed 10 per cent.

Now that the supercharging of aero engines has been shown to be a possibility, it is necessary, in order to take full advantage of it, to provide a variable pitch propeller; these will also almost certainly have to be of metal. Work is therefore in hand in this direction at Farnborough, and I trust that it will be found possible to do all that is necessary without a disadvantageous increase in weight or complexity.

The ability to fly off or land on the deck of a ship is becoming increasingly necessary. Development work to this end is in hand, and I hope the future will show that amphibians as well as aeroplanes will he easily capable of being used for this purpose. It is very necessary that they should, since descents onto water cannot always be avoided. and "landings" of this kind with aeroplanes are liable to be expensive. Experiments are in hand to examine into the sea-keeping abilities of the large N.4 flying boats. These weigh some 30,000 lbs. and have engines giving a total of 2,600 hp. It is hoped they will prove themselves good sea going craft.

And what of the helicopter? It is difficult to know what to say. Efforts are proceeding and public money is being spent; we shall, I hope, be rewarded for our foresight. Mr. Brennan's helicopter has flown to tbe extent of lifting the

Digitized by Google

pilot and 250 lbs. useful load—an encouraging preliminary flight.

Much public attention has beeen drawn to the tests made this winter on different types of fuel tank proposed by various designers. As is generally known these tests were made by inflicting on the tanks submitted a destruction experiment analogous to that of a heavy crash.

The difficulties in regard to the construction of fuel tanks were brought home during the War. It was soon found that the use of a suitable rubber envelope would prevent petrol from leaking from a small bullet hole, but the problem to be solved was a much more difficult one than this. If an empty fuel tank were fired at, a small hole would be made in the metal wall at entry and another at exit. If this, however, were done with a full tank the size of the hole at entry would not be changed, but the exit hole would be enormously increased in size, sometimes amounting to the blowing out of the far side of the tank. The latter effect was no doubt due to impulsive pressure in the liquid, but the right steps to take in order to minimize its effect were not so easily apparent. As is now generally known something very close to a solution was found in the introduction of a very thin walled tank coated on the outside with rubber and known as the Imber tank; it was, however, somewhat heavy, and was not considered to be entirely satisfactory as a fuel container under the conditions of a crash. When a tank full of petrol crashes there is initiated in the mass of the liquid an intense impulsive pressure not very dissimilar to that which is created when a high velocity projectile is suddenly brought to rest in the first few inches of the penetration of the liquid mass. To test the Imber tank, two Sopwith Camel aeroplanes were fitted with main and gravity tanks of this pattern and dropped, with engines going, from Airship R.33. The intent was to stimulate a spinning nose-dive crash with engines running and all possible causes of fire on impact free to operate. In the first test the main tank was burst by the impulsive pressure and a mad spray of petrol hot up; the gravity tank did not suffer so badly. In the second test the engine did not open out fully and the crash was less severe; both tanks survived and there was no spray or leakage of petrol. In neither case was there a fire.

Materials

The work of the Materials Sub-Committee of the Aeronautical Research Committee has led to the undertaking of researches of very great importance, not only for the future of aircraft construction, but for the engineering industry generally. On the latter, however, this is not the place to dilate. The special need in aircraft construction which differs from previous engineering experience is the enforced weight limit. The long confirmed custom of measuring the tensile strength of a material and then dividing this by some "factor of safety" of 5, 6 or 7 is inapplicable to aircraft since the resulting structure would be far too massive. In aircraft, perforce, finer limits have to be worked to and this renders it essential that the logical basis of design should be closely examined. The result of this scrutiny is to show the need to think rather of fatigue limits than of ultimate stress limits. The great difference betwen these two methods is seen in the effect of a tool mark or scratch on say a crank-shaft. Under a steady stress, local yielding would quickly absorb the minute area of high stress, but under an alternating stress the sensitive area is pulled to and fro until an appreciable portion of the shaft is weakened, and breakage results. A study of these matters is bringing forward new methods of testing, and it has, moreover, thrown light on that "scientific puzzle," the spiral fracture of a shaft. Work at Farnborough has shown the ideal limits for tensile strength and with certain substances this limit has, temporarily, been very nearly attained. I need not dilate on the immense importance of these possibilities to all engineering work, and to that of aircraft especially.

Tests on the fatigue of the materials used on aircraft are being carried out at more than one center. Investigations on this, or allied subjects, are being undertaken at the Universities at Leeds, Edinburgh, Bristol and Birmingham, in addition to researches at the National Physical Laboratory and elsewhere.

Perhaps the most troublesome material in present-day aircraft is the rubber tubing used for conveying petrol. It has to be of the "P.R." or "petrol resisting" quality, and it seems unfortunately to be the case that the effective life of this rubber is but six months, so that by the time it has been shipped to a distant Air Force center and been passed into store for a moderate time, a large proportion of its effective life—and sometimes the whole of it—has vanished. To avoid this serious difficulty the Royal Aircraft Establishment has fitted machines with piping of copper; but it is unfortunately much more difficult to fit stiff pipes than flexible ones. Happily, however, the "petroflex" piping devised by Mr. Blaisdell affords a very useful means of avoiding both the rapid aging of the rubber and the stiffness of the copper. Petroflex in rather a wonderful material. It is made up of some ten layers, glued together, of the intestines of Chinese hogs, of which, fortunately, there seem to be illimitable numbers. Around these are layers of canvas, fire-proofed. Outside this in turn, as a final protection, is a spiral of metal wire (aluminium in the case of land machines). This tubing appears to be totally unaffected by petrol, though care has to be taken to keep water away from its inside. Experiments have shown that the piping will stand as much as 200 lb. per square inch of internal pressure. Fifty sets have been sent out to the East for trial.

A supply of the right quality of timber for building aircraft is one of the most serious responsibilities to those in charge of such matters. It has been of especial importance in the last few years owing to the world demand for timber of all kinds, and the consequent indisposition of markets to take great trouble in sorting the timber or in drying it. This bears particularly hard on aeroplane construction, and I am therefore very glad to find that Canada is no supplying spruce so carefully selected that it seems not unlikely that over eighty per cent will be found to comply with our best quality specifications. There are therefore great possibilities in this direction.

An interesting development is the introduction of non-magnetic steels for those parts of aircraft which are in the immediate neighborhood of magnetic compasses. The use of stainless steel or stainless iron has also many possible applications.

Sixth Corps Aero Plans

Plans for class room instruction for officers desiring to take the examinations for promotion in the Reserve Corps were laid March 25 at a meeting of the Air Service Officers' Association of the Sixth Corps Area. The meeting was held in the Army and Navy Club, Chicago. Major William C. McChord, Air Officer of the Sixth Corps. Area, and Lt.-Col. Morris N. Keck, engaged in the organization of the reserves in this area, gave short talks on what had already been accomplished in the way of organization and the plans for the future.

According to these officers, the fundamental basis for promotion in the reserves will be that of inherent ability, rather than promotion on the basis of seniority, as in the regular army, where, it was added, conditions were somewhat different and that promotion by seniority seemed to be the most practical method.

"I do not anticipate that the technical and general examinations which candidates for promotion will be called upon to pass will be very severe," said Major McChord. "Great weight, however, will probably be given to the candidate's demonstrated ability in civil life, his past record in the service and the extent of his present interest in the work of the organized reserves. All these things will be taken into consideration in connection with the examining board's estimate of his value to the reserves in the particular rank and branch of the service for which he is taking the examination. There are many vacancies in the grades of 1st lieutenants, captains, and higher grades which must ultimately be filled, and we are bending every effort to pick men competent to fill them. It is a painstaking and difficult task. Let me repeat that, other qualifications being equal in considering candidates for vacancies, evidence of continued and sustained interest in the difficult period that the reserve is now going through will undoubtedly carry weight with the examining boards."

First Lieut. Kenneth T. Price of the reserves gave a rèsumé of the probable line of question in the examination on Military Law. His talk will be followed from time to time by other members of the reserve, leading discussions of other subjects the examinations are scheduled to cover. Capt. P. G. Kemp, A. S. O. R. C., chairman of the association, presided at the meeting. Other reserve officers present were: Lts. Joseph P. Dunne, Homer S. Watt, Herman H. Woeltjen, William E. Bausch, Arthur H. Stanton, J. W. Schroeder, Henry T. Hemmingway, E. G. Tuttle, R. E. Ailsworth, Leo L. Leonard, C. G. Geisler, S. J. Bovey, Raymond R. Rehm, Keith Jones, Otto Grafe, Roger F. Howe, J. C. Keogh, R. C. Kuhn, M. D. Harbula and Dallas M. Speer.

THE THEORY OF THE SCREW PROPELLER*

By A. BETZ, GÖTTINGEN

THE reason why the comprehension of what occurs in the vicinity of a propeller is commonly regarded as especially difficult, does not lies so much in the complexity of the hydrodynamical phenomena as is our limited ability of geometrical presentation, which some times fails us, even in simple cases, when these have a spiral form. The mathematical treatment is rendered still more difficult by problems connected with the propeller symmetry. Aside from the above inconveniences, which are not inherent in the nature of the phenomena, the propeller offers no greater difficulties than the majority of other hydrodynamic problems. By confining ourselves to the most essential phenomena, we can represent them in a very simple fashion. It is characteristic of this simplicity that we have long had a presentation of the theory of the propeller in Rankine's propeller slip-stream theory, which is a fairly close approximation to the truth and which may be regarded as a sort of forerunner of the modern theory† of aerofoils. Only when we endeavor to acquire a more accurate knowledge of the phenomena, will the theoretical treatment become more difficult. Our knowledge is most deficient in regard to the mutual action of propeller and airplane. In this connection, we must depend almost entirely on experiments. The cause of this ignorance resides less, however, in the propeller than in the resistance of the aeroplane, which here plays a very important role. This problem of the resistance of a body moving in a fluid and the attendant loss of energy, aside from any special cases, bas thus far withstood all theoretical treatment and has had to be worked out almost exclusively by means of experiments. It is therefore natural that our imperfect knowledge of the phenomena which determine the resistance of the aircraft also hinders the theoretical treatment of the related propeller phenomena. The problems relating to the independent operation of the propeller are, on the contrary, with the exception of a few very special problems, mostly solved, at least as regards propellers with favorable shapes, which alone are of any practical importance. This limitation has the advantage of enabling us to assume as small the loss of energy from friction and the formation of fortices, over which we have the least control, as compared with the amount of energy otherwise lost, and the further special advantage that the large number of shapes which otherwise would have to be considered is thereby greatly reduced. The following exposition will consist of a brief review first of the fundamental development through later researches, which demonstrate the connection between the propeller slip-stream theory and Froude's so-called "propeller blade theory."‡

If we wish to exert a force on a body, for example, on a vehicle to overcome the head resistance, we must use some other body as a brace and exert upon it the same force, but in the opposite direction (law of action and reaction). In a moving vehicle on the solid earth, the latter is nearly always the resisting body, which, cn account of its large mass, suffers no noticeable change in speed from the reaction. The case is different, if we utilize a relatively small body which is not rigidiy connected with the earth. In such a case, the body is affected by the force of reaction and acquires a noticeable velocity. This phenomenon is very apparent in firing a cannon ball. We wish to impart a velocity to the ball and therefore a force must be exertcd upon it. The cannon is the resisting body and is given a velocity in the opposite direction to that of the cannon ball (recoil). The case is similar if we wish to set in motion a body in a fluid (air or water) by means of a propeller. We may thing of the process as follows: A mass m of the fluid is utilized for a second as the reacting body and acquires a certain velocity v. Then another equal mass of fluid is brought into play and serves as the reacting body for the next second, etc., so that in each second a mass m acquires an increase in velocity v. If S represents the propeller thrust, the force of reaction must have the same value and the acceleration v, imparted to the mass m in one second by the action of this force, is $v = S/m$.

It is not essential for us to think of the process as being divided into intervals of one second. If we represent each interval by I/nth of a second and take the corresponding 1/nth part of the mass, we obtain for the same reaction force, the same velocity and the mass accelerated *per second* remains the same. The velocity imparted to the reacting fluid is directly proportional to the thrust and inversely proportional to the mass of fluid acted upon per second. With this velocity, the fluid acquires an increase in energy amounting to $\frac{1}{2} m v^2$ per second. This energy must be supplied in addition to the useful power in order to obtain the desired thrust. It means, however, an unavoidable loss of energy.

If all other losses are disregarded, it follows from an extension of the above reasoning that the most favorable case is when the thrust is evenly distributed over the whole surface of the propeller blades. This condition would be approximately fulfilled by a propeller with very many blades. The theorems for the losses in the propeller slip stream obtained from this very simple theory are very useful for estimatign the efficiency of a propeller, since the remaining losses are ordinarily considerably smaller and not so dependent on external conditions.

The theory also gives the velocity with which the fluid passes through the plane of the propeller. It may be shown that the fluid passing through the propeller acquires half its acceleration in front of the propeller and the other half behind it. An accurate knowledge of the flow at the plane of the propeller is however much desired, since it will give us a basis for calculating the blades and the position to be given them in order to obtain the desired thrust. For this purpose, however, the results of this primitive theory are no longer entirely adequate. So long as but little was known concerning the action of the fluid on the propeller blade, there was no great need of a more accurate knowledge of the flow in the plane of the propeller. But after the investigation of the phenomena of aerofoils had laid in this respect the foundation for a more accurate calculation of the propeller blade, it was alsp desirable to increase the knowledge of the flow in the vicinity of the propeller.

There were in the main two points requiring further elucidation. In the first place, the propeller, in addition to the motion of the slip stream parallel to its axis associated with the thrust, also generates tangential motions which necessitate a slight correction to the considerations of energy and, what is more important, produce a noticeable increase in the flow through the propeller disk. In the second place, screw propellers always have had a very limited number of blades. It was therefore desirable to determine what difference this circumstance makes in comparison with the assumption of a large number of uniformly distributed narrow blades. In both directions considerable progress has recently been made. Although some points have not yet been worked out for convenient practical application, the principal difficulties have nevertheless been overcome.

The investigation of the rotation of the propeller slip stream is closely connected with the above-mentioned considerations of the simple older theory. Simply, the propeller torque is substituted for the thrust. The connection between the individual quantities is indeed considerably more complex in this extended propeller slip-stream theory than in the older theory, and the calculations are more difficult. But after the requisite laborious calculations have once been made, the results can be expressed in the form of curves, which can serve as the basis for practical applications.*

The second point, in which the old propeller slip-stream theory needed to be supplemented, was the assumption that the thrust could be distributed at will over the surface of the propeller disk, which holds true to a certain degree for a propeller with very many narrow blades, but certainly not for an aeroplane propeller with two blades which cover only a very small portion of the propeller disk. It may however be here noted that the difference in comparison with the uniform distribution is not so great as appears at the first glance. On account of the revolution of the propeller, its blades exert a pressure at every point of the propeller disk, only not simultaneously and continuously, but periodically, always again at another place.

For the treatment of this propeller with widely separated blades, there is a very useful method which was developed principally in connection with the theory of aerofoils and has already been very successfully applied in that connection (Compare the article, Betz, "Einführung in die Theorie der Flugzeug-Tragflügel," Die Naturwissenschaften, Vol. 6, p. 557). A field of well-defined vortices is connected with the distribu-

c) considering finite number of propeller blades.

tion of the propeller thrust, or the lift of a wing. Since, on the other hand, the motion of the fluid is definitely determined by the vortices existing in it, we can calculate the flow from the thrust distribution by means of this concept of vortices.

Such a calculation, however, consumes considerable time. An effort has been made, therefore to simplify this work. Föttinger gave a practically applicable method in his lecture before the Society of Naval Engineers (Schiffbautechnische Gesellschaft) in 1917.* He proceeded from the correct concept that the strongest vortices are restricted to definite regions, so that we can represent them approximately by single vortex lines. These lines are the propeller axis and the spiral lines going out from the tips of the propeller blades and encircling the propeler axis (Fig. 1)).

As in the theory of aerofoils, in which a corresponding approximation is employed, this simple vortex picture always performs very good service, when the flow is investigated at some distance from the vortex lines. That the picture of the flow in the vicinity of the individual vortex lines can no longer agree with reality follows from the fact that the theoretical velocity in the immediate neighborhood of an indefinitely thin vortex line is infinitely large. If we wish to investigate the flow in the vicinity of the vortex field, more especially, for example, at the place where the blade itself is, we must have as a basis more accurate data on the distribution of the vortices, that is, on the distribution of the thrust along the blade.

After it had been demonstrated by the theory of aerofoils (in which the same difficulties occur, though to a lesser degree) that the most favorable lift distribution gave very simple flow relations, the idea suggested itself to investigate as to whether, for the propeller also, the most favorable thrust distribution is not characterized by very simple flow relations. As a matter of fact, perfectly analogous laws for the propeller can be derived by proper modifications of those employed for aerofoils.†

The most important one of these laws reads: The flow behind a propeller which has the least loss of energy agrees with the ideal flow about rigid screw surfaces displaced axially backwards. The shape of these screw surfaces is that which is cut in the fluid by the propeller blades in their motion. The speed of the displacement depends on the magnitude of the thrust.

* Föttinger, Neue Grundlagen für die theoretische und experimentelle Behandlung des Propellerproblems, Jahrbuch der Schiffbautechnischen Gesellschaft, 1918, Vol. 19, p. 385.

† A. Betz, Schraubenpropeller mit geringstem Energieverlust, with an appendix by L. Prandtl, Nachrichten der Gesellschaft der Wissenschaften zu Göttingen, Math. physik. Kl. 1919, p. 193.

However simple this statement concerning the flow generated by a propeller with the most favorable thrust distribution may appear, the problem is nevertheless not entirely solved by it. The mathematical treatment of the flow about such a displaced screw-surface presents very great difficulties. Prandtl has given an approximate solution of this problem in an appendix to the writer's article mentioned in the footnote. Though this solution does not give entirely accurate values, especially for the two-bladed propeller, it is perfectly satisfactory however for practical purposes.

Fig. 2 represents the most favorable thrust distribution, as determined by the old propeller slip-stream theory and also by the later improvements of the same. The thrust per unit surface is represented for the different distances r from the axis of the propeller. In case c, the thrust, which is here concentrated on the blade, is to be thought of as uniformly distributed on the circumferences belonging to the corresponding radii. In the old propeller slip-stream theory, the thrust is evenly distributed over the whole surface. With the consideration of the slip-stream rotation, we obtain a pressure drop at the axis and, with the consideration of the finite number of blades, we obtain also a pressure drop at the blade tips.

In deducing the laws of the screw propeller with the most favorable thrust distribution in the case of a finite number of blades, it has been assumed that the thrust is so small that the flow velocities generated by the propeller can be regarded as small in comparison with the proper motion of the propeller. We can, however, by foregoing strict mathematical accuracy, but without any error worth mentioning, so modify the laws that they will also hold good for more heavily loaded propellers.

In all the preceding discussion it has been taken for granted that we possess in the propeller blades a suitable device for exerting forces on the air, which will produce the desired thrust. No knowledge has been gained however as to the necessary shape of the blades for obtaining the desired effect nor as to the loss of energy due to the production of pressure by the blades. These data may be supplied by a method entirely different from the preceding. Its principles were expounded by Froude in 1877. Both theories, the propeller slip-stream theory and the propeller blade theory, long existed side by side, without our being able to give an entirely satisfactory explanation of the real connection between them. Knowledge of the phenomena in the vicinity of aerofoils, and more especially of the influence of the span on the resistance, first shed light on the corresponding phenomena in the vicinity of propellers.

If we assume that the effects of the individual parts of the blade, in its motion through the field, are independent of each other, we only need to determine experimentally, once for all, the forces arising in connection with the motion of definite cross sections, in order to calculate from them the forces acting at every point of the blade. The magnitude and direction of the velocity of the particular portion of the blade is indeed given by the two components, the circumferential and the forward motion. From the forces acting on the individual portions of the blade, the thrust and torque of the whole propeller can then be readily calculated. In practice, this method has the important advantage of giving the relation between the thrust and the torque, on the one hand, and the shape of the blade, on the other. Unfortunately, the assumption that the individual parts of the blade do not interfere with each other in their effect, is not correct. In practice, we may, to a certain extent, avoid this difficulty by taking as the basis of the calculation for each propeller type, somewhat different section characteristics, so selected that the resulting values for the whole propeller agree with the experimental values.

The propeller slip-stream theory, especially in its improved form, now gives us the basis for determining the mutual influence of the parts of the blade, so that, in calculating the shape of the blade, we can get along with certain section characteristics, which have been determined once for all. As we have already seen, the fluid has acquired a certain added velocity in passing through the propeller disk. Consequently the motion of the blade section relative to the fluid is dependent not only on the forward and circumferential speed, but also on this proper velocity of the fluid. In this acquired velocity, expression is, however, found for the whole influence exerted by the remaining parts of the propeller on the effect of an individual section. The connection between the acquired velocity and the section characteristics is especially manifest if we compare the loss of energy, as given by the propeller slip-stream theory, with the loss appearing at the blade in consequence of this added velocity. When we thus combine the propeller slip-stream and propeller-blade theories, we obtain a complete theory, corresponding well with facts, of the screw propeller operated by itself. The propeller slip-stream theory gives the action of an ideal propeller which, among other things, forms the basis for the correct application of the propeller-blade theory. The latter clears up the additional phenomena which depend on the special properties of the blades and more especially the magnitude of the losses at the propeller blade, not considered in the propeller slip-stream theory.

It is intended to show, by the above explanations, that the new theories present the possibility of investigating the phenomena in the vicinity of a propeller, so as to be able to calculate its action on the basis of fewer experimental values. As already mentioned, there is still much work to be done in reducing the methods to a convenient form for practical application. There is also much still to be investigated experimentally. Aside from all questions concerning the mutual effect of propeller and aeroplane, there are the characteristics of the blade sections, which still require thorough investigation. Although we have very accurate values for aeroplane wings, it is still uncertain whether these values can in all cases be applied in their present form to propellers. The centrifugal force of the revolving propeller may well cause deviations. Furthermore, at high velocities, the compressibility of air, as likewise the so-called cavitation in water, plays a certain role. There is still, therefore, in spite of all theoretical progress, a rich field for experimental activity in connection with the screw propeller.

COMMERCIAL AVIATION DEVELOPMENTS IN EUROPE

By W. KNIGHT, M. E.

(*Continued from page 3*)

ITALY

In Italy, unlike the other countries we have discussed so far, the Government has taken a surprisingly limited interest in the development of civil aviation, whereas after the war, in other countries, the Governments have done all that was possible in order to encourage the establishment of aerial lines and in keeping alive the aircraft manufacturing industry. In Italy, due to either or both the lack of funds in the budget to devote to aeronautics and the lack of a well defined program in aeronautics, we find that since the war the burden of keeping alive aeronautics in Italy has been thrown entirely on the shoulders of aircraft manufacturers. Under the circumstances, it is rather remarkable what has been done by them in the last two and one-half years, with practically no orders from the Government and thrown on their own resources for finding markets for their products.

Aircraft manufacturers in Italy have been devoting all their efforts since the war in creating a demand for Italian aircrafts abroad, and the few good firms that are still in existence are finding that their efforts are meeting with a good success.

The skill of the Italian workers, the ability of Italian aeronautical engineers, which is of a high order of excellence, and the comparatively low cost of labor in Italy, due to the exchange situation, makes it easy for Italian aircraft manufacturers to sell their products abroad and to keep from disbanding at least the nucleus of their manufacturing and designing organization, which during the war was composed of almost 500,000 men.

The most important firms which are still in the market as aircraft manufacturers are: the Ansaldo, the Caproni, the Breda, the Fiat, the Macchi and the Savoia. The last two having particularly specialized in the design and construction of seaplanes and hydroplanes, which can compete with similar construction made by other nations, some of their types being distinctly superior to corresponding types built by other nations. These two firms are doing very good export business and are supplying hydroplanes to foreign navies besides the Italian Navy. The Ansaldo Company has built a number of aeroplanes for passenger service of a very good design and well adapted for such service. The Fiat Company has built the best wooden aeroplane for commercial purposs, whicch has been flown so far. This machine was designed and constructed by Rosateli, (one of the most genial aircraft designers), for making the flight across the Atlantic, which, however was never attempted. The Fiat Company has also designed two aeroplanes, one for six and the other for ten passengers and a three unit power plant with a single propeller. The Caproni firm has built last year, a Giant aeroplane for 100 passengers, which, however, during the trial test, was partially smashed up and is now being reconstructed.

Italy has always been very active in dirigible construction. The Italian dirigible (of which we have recently acquired a unit, the "Roma," now destroyed) is the semi-rigid type. Dirigibles of this type have been made at the "Royal Aircraft Establishment" in Rome, operated by the Italian Government directly, and dirigibles and balloons both for the Italian Government and foreign Governments have been made there. There is now under consideration by the Italian Government, a project for selling the "Royal Aircraft Establishment" to a civilian syndicate and let the syndicate take care of the construction of Italian dirigibles. It is anticipated that such a move, if the proposed project is approved, will give a more healthy life to the dirigible industry in Italy.

A number of aerial navigation companies have been started in Italy, but none of them has established and operated a regular service on some definite route. The activities of these companies have been mainly limited to advertising flying as a new means of transportation and to make flights with passengers upon request. Among the most active of the various companies, the S. A. I. A. M., during its first year of operation from June first, 1920, to May 31, 1921, made the following record:

	Hours of Flight	Passengers Carried
June 1920	96.45	365
July "	101.35	591
Aug. "	160.12	453
Sept. "	173.30	520
Oct. "	125.45	374
Nov. "	110.13	215
Dec. "		
Jan. 1921		
Feb. "	90.11	238
Mar. "	37.50	139
Apr. "	45.30	217
May "	56.40	240
Totals	998.11	3352

Another company, the S. A. C. T. A., is going to open up, next summer, the line between Genova-Porto Torres and Porto Torres-Cagliari, between the mainland and the Island of Sardegna.

A regular aerial service has been organized and it is operated by the Government in one of the Italian colonies in Africa between Tripoli and Hons, making one trip per week for carrying mail. The passenger service is limited only to Government officials and Government employees travelling in the service of the Government. The passenger service is effected with 450 H. P. Caproni machines and the mail service is effected with S. V. A. machines. This is only a short line, only 62 miles long, and a very small attempt to establish aerial mail service in Lybie.

No aerial mail service is in operation in Italy at the present time.

Contrary to what the French Government is doing in establishing hydroplane bases in the Mediterranean, very little is done in Italy in this direction, in spite of the fact that the geographical location of Italy in the middle of the Mediterranean, would make it extremely expedient to develop and to maintain a large number of hydroplane bases. The hydroplane port service is operated by the Italian Navy only. Only in Naples, Taranto and Brindisi, the service is well organized. In the hydroplane ports of Venice and San-Nicolas-Varano, the service is only partly organized. In the hydroplane ports of Livorno, Orbetello, Ostia, Syracuse, etc., the service is very poorly organized, lacking as they are in sufficient fuel and oil reservoirs and spare parts. What has been done very efficiently by the Government has been the organization of a very good aerological service for supplying aerial navigators with all the required data. The technical services are well organized and have a very good personnel, working at technical investigation and research work, but they are always struggling along with insufficient funds to carry on their work.

The Italian Admiralty has undertaken the installation of lights on the airdomes of San Remo, Spezia, Orbetello, Centocelle, Naples, Trapani, Catania, Taranto, Brindisi and Pola. These lights, however, are on only when so ordered by the command of civil aeronautics or the Admiralty.

In Italy, there is at the present time, quite a mess of civil, military and naval aviation with no well defined limits, and interfering with each other, thus handicapping any civilian initiative for establishing regular aerial services in Italy. The public press, the Aero Club and the Society of Aeronautical Engineers, have been lately conducting a quite lively campaign in order to have this tangle straightened out and for obtaining the establishment of a healthy civil aviation in Italy, and all indications are that in the course of the current year something will be done in that direction.

Italy, due to its geographical position in the middle of the Mediterranean is a very important jumping off point for the international lines plying between central Europe, the North African Continent, and the Balkans, and there is no doubt that as international aerial lines are established and developed, Italy will play a rather important part in the commercial aviation game, especially considering that the aircraft manufacturing industry thre is capable of producing good aircraft at a good price.

The aeronautical activities of Italy, so far, have been limited to a number of raids and competition in international aero-

Digitized by Google

nautical events where the Italians have obtained a number of important prizes during the last two years.

GERMANY

We have seen so far that one of the reasons why commercial flying has not been a financial success in France, England, Belgium and Italy is that the aircraft used for commercial services were not adapted to the kind of service required of them. In almost any case of commercial exploitation by aerial lines in Europe, aeroplanes which were originally designed for war services were modified so as to allow for their being used as commercial carriers. This handicap, under which commercial aviation was born in Europe, is due to the enormous number of military aeroplanes left over when the war stopped.

The aircraft manufacturing industry has also been handicapped by the fact that aeroplanes were sold by the Governments from the stocks left over after the demobilization, at such a price that aircraft manufacturers could not compete with the Government in selling tbeir products.

In Germany, we find an entirely different condition prevailing after the war. The treaty of Versailles practically wiped out all aircraft existing in Germany at the time when the Armistice was signed. All the aeroplanes and flying equipment had to be handed over to the Allies so that Germany, right after the war found itself with no aeroplanes.

Two opposite tendencies were sbown in the supreme council regarding the future of aeronautics in Germany. French, Italian and Belgian experts were in favor of prohibiting to the central empire the construction and the use of flying machines (both aeroplanes and dirigbles) for an indefinite period of time, until such a date as the rest of the world might feel confident that the defeated nations had abandoned any projects of future aggression. This tendency was opposed by English and American delegates, wbo finally succeeded in carrying the point.

The decision arrived at was that military aeronautics had to be suppressed in Germany, that all the existing aeronautical material had to be either destroyed or handed over to the Allies, but at the same time it was agreed that commercial aeronautics could be born in Germany, although a number of limitations were imposed on the German aircraft manufacturing industry, which, however, inside of the next few months will be entirely removed, Germany having complied with the conditions imposed on them by the Treaty of Versailles.

Due to the situation brought about by the Peace Treaty, commercial aviation was born in Germany without the handicap of the existing large number of war aircrafts, which in the other countries made it difficult for the aircraft manufacturers to design and manufacture commercial aeroplanes well adapted for commercial use, when such large numbers of aeroplanes could be bought at an extremely low price from the Government and transformed in a more or less inefficient way to commercial use.

The consequences of the situation is that since the war, Germany has developed some exceptionally good commercial aeroplanes, and has built a fleet of such planes which are far superior to those used by the other nations. They are more efficient, and better adapted to commercial exploitation. They are so much so that the progress made by Germany in aeronautical construction is eliciting some uneasy feelings throughout the rest of Europe. On October 13th, of last year, in an editorial appearing in the London *Times*, some sanctions against further expansions of German aeronautical activities were invoked. It was pointed out in that editorial the very obvious fact that the technical progress made by the development of the aircraft manufacturing industry in Germany constituted a potential military danger for tbe future, considering the fact that a commercial aeroplane can, without much trouble, and in a very short time, be transformed from a commercial flying machine to a war engine. These conclusions are obvious and they are well in accordance with the opinions expressed hy the French, Italian and Belgian experts advocating the suppression of all aeronautical activities in Germany for an indefinite period of time. It is rather surprising that in some British quarters, anxiety should be voiced at the present time about the future of German commercial aviation, which is indebted for its very existence to the British and American stand taken in the Supreme Council.

Anyway, at the present time, nine strong and well organized aerial transport companies are in existence in Germany, and are making plans for future developments, which shall be particularly interesting in establishing communications between Germany, Sweden, Holland, the Balkan States and Russia. In Russia, especially, we might expect that the Germans will be in the future a dominating factor of the establishment and development of aerial transportation.

It seems that aeroplane service over a direct route between Germany and Russia will be put in operation in the spring, cutting the time between Berlin and Moscow to only 22 hours. Aeroplanes will be used from Moscow to Koenigsburg, where arrangements will be made for direct connections with night trains coming to Berlin. The new German-Russian aircraft company, which has just been organized for this purpose, is financed by the Russian Government and by the Aero Union. The latter is owned by the Elektricitats Gesselschaft, the Hamburg-American Line and the Zeppelin Airship Company.

It is worth mentioning here that the plan of establishing connections with Russia and the rest of Europe, was conceived by France as early as the summer of 1920 when negotiations were started between the Denikine Government, the Russo-Asiatic Bank and a group of French aircraft manufacturers for the establishment of aerial lines in the Donetz Basin for the transportation of mail and freight.

The proposal advanced by the Russians was, first: the French aircraft manufacturers were to supply the flying materials needed, aeroplanes, equipment and spare parts. A company would have been started for the exploitation of the aerial lines, and French aircraft manufacturers would become stockholders in this Company to the extent of the sale price of the material furnished, the balance of the capital needed being subscribed by the Russo-Asiatic Bank. The dividends of such a business enterprise being paid to French aircraft manufacturers in fuel for an equivalent value. These conditions were accepted by the aircraft manufacturers with the exception that they asked that half the price of the material supplied by them, be paid in francs, so that they might become stockholders in that company to the extent of one-half only of the sales price of their material. The payment of dividends in fuel was accepted. These negotiations could not be brought to a conclusion on account of the downfall of the Denikine Government, but the points agreed upon show at least that French aircraft manufacturers were willing as early as two years ago to risk their benefits in such an enterprise. Apparently the Germans have now succeeded in entering into an agreement with the Soviet Government in Russia for establishing aerial communications between Germany and Russia. There is not the least doubt that the first initial step will be followed later on by further expansions.

When we consider the large land extent of Russia, the rudimentary state of railways, the great distance separating commercial centers and the enormous commercial opportunities to be found in Russia, we can easily realize how important it will be to establish and operate lines such as Petrograd-Moscow, Kieff-Odessa-Italta or Petrograd-Moscow-Kharkoff-Wladkovkaz, covering these distances in 24 hours. The trip Moscow-Tokio or Moscow-Pekin, trans-Siberian lines, could be made in three days. The international lines, Paris-Moscow in 24 hours, Berlin-Warsaw-Moscow in 10 hours, Odessa-Bukarest in 3 hours, Petrograd-Stockholm in 5 hours, Petrograd-Copenhagen in 9 hours, Odessa-Constantinople in 4 hours, Odessa-Vienna in 6 hours, London-Calcutta passing through Tarnopol, Astrakan, in three days, are of such importance that I do not need to emphasize.

Various lines are now in operation in Germany between Berlin-Leipzig, between Nuremburg, Munich and Augsbourg. The operating companies are subsidized by the Government and the Deutsche Luft Reederei of Berlin, in 1920, received 15 millions of marks subsidy from the Government. This company is one of the most important and the best organized of the aerial transport companies in Germany.

At the general meeting of the Deutsche-Luftfahrerverband, on October 22, 1921, the consolidating into one single company of the Deutsche-Luftfahrerverband, the Aeri-Klub von Deutschland and the Allgemeine Deutsche Flugverbang was decided upon. The new company thus formed will take the name of Deutsche Luftfahrtverband.

Most of the aerial lines in Germany suspended their activities in October of last year and the service will not be resumed before March, 1922. In the meantime, it is most likely that new lines of operation have been taken into consideration and by next summer we might anticipate quite a lively start of commercial aviation in Germany.

Besides the aerial lines as mentioned above, another line was opened last year between Dantzig, Koenigsberg and Memel. Also in September of last year a line between Riga and Reval was opened up. This line is operated in connection with the Dantzig, Koenigsberg, Memel, Riga line.

Departure from Dantzig taking place three times per week, Monday, Wednesday and Friday, starting from Dantzig at 9 A. M., starting from Koenigsberg at 11 A. M., and starting from Memel at 1 P. M., arriving at Riga at 3.30 P. M.

Departures take place from Riga every Tuesday, Thursday, and Saturday, starting from Riga at 10 A. M. arriving at Reval at 12.30 P. M.

For the return trip. departures from Reval occur every Monday, Wednesday and Friday, starting from Reval at 1 P. M., arriving at Riga, 3.30 P. M.

Digitized by Google

Departures from Riga every Tuesday, Thursday and Saturday. Starting time from Riga, 9 A. M., starting time from Memel, 12 noon, departures from Koenigsberg at 2 P. M., arriving at Dantzig at 3.30 P. M.

Mail matter is accepted on this line with ordinary postage stamps for foreign mail. Mail matter starting from Berlin can reach Riga after 38 hours. This is the first attempt to start Air Mail Services in Germany.

Before concluding, we might add that scientific research work in aerodynamics and sciences thereto allied has been conducted throughout the war and since the war by the Germans with the most gratifying results, in fact, we might safely say that the Germans have contributed to the development of aeronautics as a science and as a branch of engineering more than any other nation up to the present time.

In dirigible construction it is well acknowledged by everybody, the leadership of the Zeppelin and the Schutte-Lanz firms in rigid dirigibles design and construction. Also in metallic aircraft construction, the advancement made by Germany in this line is well known. Metallic aeroplanes made by Junkers, by the Zeppelin firm and by Dornier are well-known, and it is admitted by everybody that in this line of aircraft manufacturing industry, the Germans are so far unexcelled by other nations. (*To be concluded*).

THE AERIAL JOURNEY FROM LONDON TO PARIS

A SCOTCH clergyman, Rev. H. S. M'Clelland, writes an interesting story of his journey by air from London to Paris in a recent issue of the Glasgow *News*, as follows:

"The day on which I travelled by the London-Paris air mail, the conditions were perfect for flying; scarcely a breath of wind on the ground, hardly a cloud in the sky. We arrived at Croydon (London) about 10:15. Here are the offices and aeroplane sheds of all the great air lines to the Continent—the Handley-Page, Instone, Grand Express Aeriens, &c., each flying its own 'balloon.' A huge star in red sandstone marks the center of the aerodrome. Away to the left the new anchoring mast for airships rises several hundred feet in the air. A score of aeroplanes de luxe, all of them of tremendous wing-spread and colossal engine-power, line the ground, around one of which, a huge Vickers-Vimy, Rolls-Royce, Limousine, of 470 h. p., a group of mechanics are busy. We knew instinctively that it is for us they were waiting. Five minutes more and we are through the Customs, have had thirty pounds of free luggage carefully weighed, and are being helped into the car of this leviathan of the air. I found myself sitting in a well-ventilated saloon with ample room for movement. There were eight passengers in the car, and we sat four-a-side, with a small passage down the middle.

"Through the window I can see our young pilot putting on his air-mask A yellow bag, wax sealed, is handed to him. It is the air mail. He flings it into the driving seat and jumps in after it. Down below several mechanics in brown overalls are swinging the long blades of the propeller to and fro. My watch records half past ten.

"'Stand clear!' rings out an order. 'Contact! Contact, sir!' The great engine opens with an earth-shaking roar, and grows louder and louder. Someone kicks the blocks away from the runners. The huge machine leaps forward like a greyhound from the leash, and gathering speed as it goes, it travels at a terrific rate for the end of the aerodrome. This, of course, is the critical moment of the ascent. We appear to be making straight for a clump of trees. If we don't take the air soon . . . Ah! I thought so. The jolting, bumping ceases, and the slight roll from side to side tells us that our 'runners are up,' that we have left the ground. Now we are facing the aerodrome again, but the sheds are several hundred feet beneath us, and a group of Lilliputian figures are waving us farewell. Rapidly we climb to five thousand feet, and the scene below grows passing strange. The dull yellow dauhs, with the ditches between them, that marked the southern suburbs of London soon pass behind the Kentish hills. Now we are passing over open country, where the cultivated fields look like the tiny squares on a patchwork quilt, whose dominant colors are green and gold. Toy motor cars, with clouds of dust behind them, crawl sleepily along the white road-ribbon that covers the country side. It is interesting to study the various patterns of the corn-sheaves that are standing in the yellow fields. The black threads that seem to tie the towns together are railways, on one of which a train is disappearing into a tunnel. It looks like a tired worm crawling wearily into its hole. Those black spots, here and there, are farmsteads. Towns you see long before you reach them, and you see them all at once. They never look beautiful from the air. They remind one of warts.

"That shining string of diamonds is the Medway, dancing in the sun. All this you see if you look down. To look straight out of the window is to see the huge struts and mighty wings of this great bird of passage, upon which for another hour our very lives depend. The aeroplane rolls in the air like a ship. Some of our number are showing signs of air-sickness, though 'air pellets' were given to us all before we embarked, with fullest instructions as to their use if we 'felt queer in the air.'

"We left the English coast at a quarter past eleven, somewhere between Hythe and Folkstone. We had descended to 1,500 feet and could plainly see the watchers on the sands. No language of mine could describe the magic of that crossing. Behind us the rolling downs of Kent; beneath us the dancing waters of the Channel; before us the pine-clad sand-dunes of the Pas de Calais. Only five ships of any kind were visible beneath us, the largest of them a P. and O. liner, looking like the sort of thing the London children play with on the Round Pond in Kensington Gardens.

"But already the Irisnez lighthouse was poking its long nose up at us as we passed over her, Boulogne was spreading itself out beneath us, has passed behind us, and we were flying above the ruins of the British hospital camp on the brown Etaples sands. I looked at my watch. It was exactly eleven minutes since we left the English shore! We now turned due south, but climbed gradually to six thousand feet to get above the haze driving in from the sea. Little could be seen with any clearness from that altitude, save the long, straight public roads for which France is so famous, with the black shadows of the poplars lying flat on the white surface. As we passed over Montreuil, about 11:45, for three years the British Army G. H. Q., I found myself wondering how many German bombing planes had searched these areas in vain. Twelve o'clock found us flying over the battlefield of Crecy. A few minutes later Abbeville lay behind us, and we were across the wide estuary of the Somme. We had now been in the air for nearly two hours, and even for our youngest passenger, a young girl of seventeen, the novelty of the experience was passing. We began to take more note of each other. A passenger in the back seat is reading a French novel. Several of us are busy photographing the interior of the saloon, and vainly attempting to get 'exteriors' as well. One timid friend, to whom courage is now returning, asks his neighbor to try a snapshot of him! 'I guess I'd like a memorial of this fool trip,' he says, 'for they'll be flying to Mars before I take another!' 'What do you mean?' replied a Toulouse pilot. 'What do you mean, you'll never have another? Why I'll be flying you next week to Rabout!' 'I guess you won't,' drawled the American, 'the next time I'm up as high as this, the good Lord'll be takin' me to glory!'

"It was now 12:40. We had passed over Poix and Crevecour, Beauvais and Pontoise, when, away in the distance, with the silvery Seine, like a shining serpent, winding all about her, I caught my first glimpse from the air of the gay French capital, nestling like a jewel in a velvet casket, in the woods of Chamberg and Versailles. Suddenly, and to most of us unexpectedly, for we were still a long way from Le Bourget, the roar of the great engine ceased, the air became strangely still, and we felt ourselves falling earthwards, and turning as we fell. Our American friend kept his eyes fixed on the height indicator. 'Six thousand feet!' he read breathlessly, 'five thousand, four thousand, three—' With a mighty roar the engine started again. We rose rapidly a thousand feet, turned on our track and came down in a sweeping curve. The American could stand it no longer. 'For God's sake, Mr. Pilot,' he cried, 'don't change yer mind! Keep on goin' down. Keep on goin' down!' The pilot evidently knew his own mind quite well. We came down the remaining half mile in a series of volplanic spirals that landed us right over the star in the center of the aerodrome.

"We landed at 12:46, having covered the 260 miles between the two capitals in two hours and a quarter, an average of two miles a minute! Half an hour later I was lunching at the Hotel Continental with some of my fellow adventurers. 'What are you doing with yourself this evening?' I asked of one of them in whom I had already found a friend. 'I'm thinking of going to the "League of Notions?"' he replied. 'Do you know anything about the show?' '"The League of Notions?"' I answered in great surprise, I didn't know that was to be seen in Paris.' 'It isn't,' came his quiet answer. 'I'm flying back to London by the four o'clock plane.'"

NAVAL and MILITARY AERONAUTICS

Air Service Denied Participation in National Rifle Matches

The Army Air Service has found it necessary to abandon its plans for participation in the National Rifle Matches to be held at Camp Perry, Ohio, this coming fall. Basing his request on the fact that the Executive Committee of the National Board for the Promotion of Rifle Practice contemplates the participation in the National Rifle Matches of a team from each of the combatant arms of the Army, the Chief of Air Service, on February 27, 1922, made application to the War Department for the participation of the Air Service in these Matches, stating that the necessary personnel to form a team is available this year, and that such participation in these Matches would stimulate interest in the manipulation of small arms among both officers and enlisted men. It was also stated that it is planned to assemble about 42 officers and enlisted men, exclusive of a team captain and team coach, at the National Guard Rifle Range at Virginia Beach, Va., on or about June 1st, for preliminary training and tryouts, after which a final selection would be made of 24 men who will proceed to Camp Perry as the Air Service contingent.

The War Department's decision, disapproving the application, is based on the fact that only about one-third of the entire personnel of the Air Service is armed with rifle, and that the units are so equipped merely for purposes of defense.

Students Finish Primary Training

The Academic Board at Carlstrom Field met on March 7th for the purpose of passing and making recommendations on the class of student officers and cadets who commenced the course last September and who have now completed their primary training. Some fourteen officers and twenty-five cadets appeared before the board and were recommended for advance training, 10 per cent. of the class being assigned to pursuit training, 25 per cent. to bombing and 65 per cent. to observation. Orders have been requested for the assignment of this class to advance training schools.

Reserve Squadron Stages Aero Circus

San Jose, California, the home of the 440th Aero Reserve Squadron, was treated to an unusual event the latter part of February, the occasion being the Flying Circus held at that place under the auspices of that squadron. Some of the commissioned personnel from Crissy Field, Presidio of San Francisco, Calif., including Major George H. Brett, commanding officer; Captain A. W. Smith, Flight Surgeon, and Lieutenants Batten, Maxwell, Kiel, Liggett, Patrick and Catlin, flew to San Jose to witness the event. The Circus attracted approximately 20,000 spectators and had successfully run the gaunt of aerial stunts peculiar to aerial circuses, such as spectacular stunt flying and aerial acrobatics, with Mr. Pangborn, civilian pilot, Captain Lowell Yerex, famous English "Ace," and "Jinx" Jenkins, known from one end of the Pacific Coast to the other for his feats of aerial daring, as the principal participants, up to the last act.

As has been the case during previous circuses in which "Jinx" Jenkins had participated, he was concluding his performance with a parachute jump from an altitude of approximately 2,500 feet. He had scarcely jumped from the plane, however, when it was evident to the horror-stricken onlookers that his parachute had failed to open; and despite desperate struggles up to almost the very moment when he struck the ground, "Jinx" was unable to make his parachute function. "Jinx" numbered amongst his friends many of the officers at Crissy Field, and the untimely death of this young man is sincerely regretted by all who knew him.

Boosting Aeronautics in California

At a meeting held on February 28th at the City Hall of San Francisco, an Air Service sector of the Association of the Army was organized. Major H. H. Arnold, Service Air Officer of the 9th Corps Area, was elected President thereof, and 1st Lieut. Robert E. Selff, Air Service, of Crissy Field, was chosen Vice-President. The object of this organization is to foster aeronautical development in general, and to create and aid in every way possible among the various branches of the Army interest in matters aeronautical.

Aero Tactical Demonstration at Luke Field, H. T.

Luke Field, H. T., was the scene of a tactical program demonstrating the different phases of aerial activities under war conditions, on Saturday, February 11th, on the occasion of the visit of Major General C. P. Summerall, Commanding General, Hawaiian Department, on a tour of inspection, accompanied by Governor Farrington of the Territory of Hawaii. All planes were on alerte. At the zero hour an HS2L seaplane took off on a reconnaissance mission, Ford's Island representing the Island of Oahu for this mission. Radio communication was established between the seaplane and the Group Radio Station (5th Group, Observation) and the observer of the seaplane reported the approach of the "enemy." Upon receipt of the message requesting that an air force be sent to drive off the landing parties, the alarm was sounded, the motors started and in a very short time five planes took off in perfect formation and carried out a dive attack and bombing raid in the harbor representing the "enemy." At the conclusion of the raid, the planes passed in review, all observers at salute. The Commanding General returned the salute and the planes circled and landed.

Next came a bombing raid of the island by one ship over the camera obscura making four shots up wind until engaged and driven off by the Fokker. Lieut. Miller then demonstrated the maneuverability of the Fokker. The bombing plane then carried out a radio-panel communications mission, establishing communication between the plane and radio truck set upon the field. At the conclusion of the mission, the message was dropped and checked made of all the shops and departments, including the barracks of the 6th Squadron.

M. B. VII Makes Another Trial Flight

The little monoplane of the Thomas-Morse Aircraft Corporation which is being tested at Mitchel Field, L. I., New York, was given its second flight on with the record at the truck. Following the flying program, an inspection was March 10th by Lieut. Fleir of the Marine Corps. The officers of Mitchel Field were eager spectators as Lieut. Fleir drove the little racing plane around the course. Again, as before, all were of the opinion that the MB VII will develop great speed. Lieut. Fleir thought she was making at least 185 miles per hour at one time. He only opened the motor up on one occasion, and then only for a brief time.

Post School at Mitchel Field Makes Gratifying Progress

After its first experimental week, the Post School at Mitchel Field settled down to its task of giving a rapid one month's course in the necessary subjects to fit a recruit or unskilled soldier for a crewman. The weekly examinations on Friday, March 10th, served as a means of eliminating those who are unfitted, by reason of lack of intelligence, education or industry, to stand the strain of rapid progress of the classes. Those who yet remain, however, about 150 in number, are working hard, making progress, and will be turned out on April 1st with sufficient knowledge of airplane and airplane motor mechanics to make them serviceable crewmen for the summer's strenuous flying activities.

Air Service Observation School in Full Swing

The ending of the sixth week at the Air Service Observation School at Post Field, Fort Sill, Okla., finds the present class beginning class room work. To date, all work has been strictly practical—actual work on engines and planes, in addition to flying, has obtained. The seventh week brings up the theory of Reconnaissance, Photography and Artillery adjustment. These subjects occupy one-half of each day, the other half, as heretofore, being devoted to flying.

The School was visited the early part of the week by a delegation of Japanese Army officers. They were shown the various activities and seemed to take much interest therein. A problem was fired for them on the miniature range. The speed and facility with which artillery fire may be directed on a target by aerial observation was very well demonstrated to the gratification of the visiting officers.

The next eight weeks will constitute the most difficult part of the course. During this period a great variety of subjects will be covered, and some thirty missions will be flown by each student, in addition to the daily routine flying.

The past week has brought with it a variety of good and bad weather; the latter, however, has had little effect upon the schedule, due to the alternate work prepared. With spring, work should proceed very smoothly, and the indoor part completed, leaving only the final stages of flying to be accomplished.

FOREIGN NEWS

France's Great 1924 Competition

From France it is reported that the prize of one million francs offered by the French Society for Aeronautical Propaganda for the "best" aero engine will probably be augmented by another million offered by the French Air Minister. But few details are to hand at the time of going to press, but it appears that the competition will be for engines of 350–450 h.p., and weighing not more than 2 lbs./h.p. It is understood that competing engines will have to pass a reliability run of 240 hours, in stretches of eight hours each, and that the total time taken in completing the 240 hours must not exceed 100 days. The competition will start on March 1, 1924, and entries must be received before December 1, 1923.

Belgian Aero Club Competition for Touring Machines

Details of the Internationa. Competition for Touring aeroplanes organized by the Ae.C. of Belgium at Brussels on June 23-25 are now to hand. The competition is open to touring machines, single-seaters or multi-seaters, whose engine capacity does not exceed 7 liters. The course is to be Brussels-Gosselies (landing) 47 km. Gosselies-Brussels-Brussels-Gosselies (landing) 141 km. on Saturday, June 24. The awards will be made for a total of 100 points, allotted as follows: 30 points for minimum of space occupied in the garage, 30 points for general economy of the engine, 25 points for slow landing, and 15 points for quick get-off. The machines entered must be on the Evere aerodrome at Brussels before noon on June 22. The prizes are as follows: The King of Belgium's Challenge Cup, to be retained by the winner for one year; and the following cash prizes: 1st prize 15,000 francs; 2nd prize, 7,000 francs; and 3rd prize, 3,000 francs. All enquiries should be addressed to Secretariat de la Commission Sportive, Aero-Club de Belgique, 73, Avenue Louise, Brussels. The entrance fee, returnable if machine starts, is 100 francs, and should be sent to the Treasurer of the Belgian Aero Club before June 10.

Cairo-Bagdad Air Mail

The British Postmaster-General stated on March 2 that the air mail which was dispatched from London on February 9 reached Bagdad on February 27. The mail due to be dispatched by air from Bagdad on February 18 reached Cairo on February 23, and letters included in it for England arrived in London on March 3.

French Air Traffic

The French Department of Aeronautics and Air Transport has issued a statement giving traffic figures in connection with the progress of commercial aviation in France during the years 1919, 1920 and 1921. Considering the handicap under which aviation has been carried on by the companies concerned, these are very encouraging. The following is a summary of the official figures:—

Year.	Journeys made.	Miles covered.	Passengers carried.	Parcels, lbs. (approz.).	Letter Mails, lbs.
1919	988	158,606	588	14,000	900
1920	2,386	529,454	1,721	110,000	9,000
1921	6,221	1,457,437	10,336	375,000	21,000

Figures which are available for the air mail between France and Morocco for 1921 are also very instructive. In the "round" journey there and back the increases have been very marked. In January, 1921, the total was 16,377 letters; in January, 1922, the number was 50,851, equal to over 300 per cent. increase. Curiously, the dispatchings from Morocco to France were greatly in excess, viz., 32,691, as against 18,160 in the reverse direction. So steady has been the growth of the air mail that it has determined the Secretary of State to augment the facilities by increasing the service between Toulouse and Casablanca from three to five times per week as from this month—necessitating a fleet of 90 craft. The following monthly figures of letters carried during 1921 speak for themselves:—

February, 12,025; March, 14,005; April, 17,179; May, 18,878; June, 22,738; July, 28,108; August, 34,283; September, 35,006; October, 40,601; November, 41,330; December, 47,235.

"Safety First" Air Prize

A prize of 25,000 francs is offered by the French "L'Union pour la Sécurité en Aéroplane," for the best safety device or scheme for flying in fog or at night submitted during 1922. Details governing the award are not yet available, but those interested can communicate with the Association at 35, rue Francois-Ier, Paris.

Seaplane Contest at Marseilles

It is announced that the Aviation Committee of the Colonial Exchequer, to be held at Marseilles this year, have definitely decided to ganize a contest for seaplanes from April 17 to 19. There will be three categories: under 150 h.p.; 150 to 400 h.p.; and over 400 h.p.

Eliminatory trials are to take place on April 17 when entered craft must ascend to 1,000 meters, and have on board, in addition to the normal useful load, sufficient fuel for 1½ hrs. flight. The course, Marseille-Monaco, is 413 km. Prizes to the extent of over 40,000 francs are offered. An entrace fee of 200 francs (returnable in its entirety) obtains, and communications should be addressed to the Aviation Commission, A. C. de France. Military competitors will take part *hors concours*, a trophy being their recompense.

To Improve Upon "Landing" on Water

In France our contemporary *L'Auto*, has raised the point of finding a verb better to define "landing" on water. Suggestions, weird and otherwise, are naturally forthcoming, amongst them being aquair, aquater, and afflotter. For our own part, we get over it by putting the trouble on to "alighting."

Gliding in Germany this Year

From reports from Germany it appears that the gliding competitions which started on quite a modest scale a couple of years ago are to assume greater proportions in the future. Not only are the Rhön competitions to be resumed this summer, but it is stated that a new prize of 100,000 marks is to be offered for the first German glider which makes a flight of 40 minutes' duration over a course similar to that of a yacht race. Presumably this means over a triangular course. The prize, it is reported, is to be offered by the Society of German aircraft constructors, after consultation with the German Aero Club, and the German Aeronautical Society. The conditions are sufficiently difficult, coupling as they appear to do a duration of 40 minutes with a specified course. One or the other might be fairly easily attainable, but the combination of the two is so difficult that one doubts whether the prize will be won for some considerable time.

Mountain Reconnaissance by Air

An officer of the Geodetic Mission in Syria has carried out recently an aeroplane reconnaissance of the zone which he is engaged in surveying. The object of the experiment was to prove whether it was possible by flying over a region, such as the anti-Lebanon Mountains, to get an exact idea of the differences in height of the summits and consequently to be able to select the points to be used as a basis for triangulation. The experiment proved very satisfactory and several weeks' time was saved.

German Aviation

The following is a translation of an article by Lieut.-Colonel Reboul of the French Army, which appeared in a recent issue of the French publication *Le Temps*:

The Ministry of War of Germany has just published regulations which enlighten us on the state of mind of the German High Command and its designs. The "Instruction on the employment of aviation to be used for maneuvers, regimental exercises and drills in tactics" is a statement in concise form of the opinions of the German High Command on the employment of aviation during the war.

Article 198 of the Treaty of Versailles prohibits Germany from keeping any aeronautical force whatever. This, however, does not prevent the Minister of War from declaring in this instruction: "In the distribution and employment of the aviation formations we have taken as a basis a modernly equipped army for use in giving decisive combats." It does not prevent the cadres of the *Reichswehr* from already undergoing training in the use of the aeroplane. In their *kriegspiele* they assign missions to it and receive information from it. They are accustoming themselves to handle it, to consider it as an arm, the collaboration of which is indispensable. They are making preparations to use aeronautics in connection with the other arms.

Doubtless the *Reichswehr* will be unable to begin the actual exercises so long as our control commissions remain in Germany. But the day they leave, the "Instruction on aviation" will immediately be put into effect. The plan being already known to all, it would require but a short time to put it into operation and have an aviation force working in close union with its command, its infantry, its artillery and its cavalry.

Chapter II of the regulations treats of the aerial formations. It provides for an exceedingly high aviation equipment for each large unit.

The Infantry division includes organically a strong squadron of two escadrilles. One of these, the reconnaissance escadrille, will be used for close missions and for observation of the battlefield. The other will work with the divisional artillery. Each of these escadrilles comprise 12 aeroplanes. The German army thus realizes the desiderata which we expressed at the end of the campaign of 1918. The division is henceforth permanently equipped with its eyes and observers. Its aviation will work constantly with the same units. They know one another wonderfully well; they have confidence in one another; they conform to one another's customs and idiosyncrasies. The results will be incomparably greater than those obtained with escadrilles that are assigned only temporarily to the divisions. At the moment that everyone begins to speak the same language the escadrille is replaced by a new one. Everything must be begun all over again.

The army corps has its own squadron which has the same composition as the divisional squadron. Its reconnaissance escadrille will specialize in photography and in night reconnaissance; its artillery escadrille will regulate the heavy artillery firing of the army corps.

The army is very strongly equipped with aviation units. The regulations provide for the assignment to it of one observation squadron, combat squadrons, pursuit squadrons and bombarding squadrons.

The observation squadron is of the same type as the divisional squadron; but its aeroplanes will as a rule be superior. They will, in fact, penetrate more deeply into the enemy lines. The reconnaissance escadrille will make distant reconnaissances and photographs of the enemy's rear areas. The artillery escadrille will regulate the fire of the high powered heavy artillery which will be directed against the enemy quarters, its parks, railways, installations and points through which it is compelled to pass.

Each army in active operations has assigned to it a combat unit with a strength of 3 or 4 squadrons. Each squadron comprises 4 escadrilles of 12 aeroplanes each. This represents a body of 150 to 200 aeroplanes which will have as its mission to take part in all the phases of the battle, both in aerial combats and in combat against the other arms. In an attack it will act with the assaulting troops, will precede the first waves, mowing down the enemy reserves and bombarding the centers of resistance.

The pursuit unit will be especially charged with the aerial fighting. It comprises from 4 to 6 pursuit squadrons, each squadron comprising 3 escadrilles of 21 planes. Its mission is to hinder the enemy reconnaissance and prevent the enemy combat aviation from taking part in the battle. It must enable its own reconnaissance aeroplanes to accomplish their mission. Its object is aerial combat. Pursuit planes should act in mass so as to be master of the air, at least during certain hours. They may be reinforced for certain missions by combat and bombarding squadrons.

The bombing aviation is less strong numerically than the combat and pursuit aviations. It consists of from 1 to 3 squadrons, each formed of 3 escadrilles of 12 planes. It is to be used in bombarding by day as well as by night.

The group of armies has only a very limited aviation force, which consists of one escadrille of 12 planes for making reconnaissance which are of special importance to it and which it wishes to entrust to observers whom it knows and can rely upon, and one artillery escadrille of 12 planes for the long-range and very mobile guns, especially those on railways, which it fires now in one direction, now in another.

The General Headquarters reserves a few combat and pursuit squadrons both for its own safety as well as for an aerial reserve. It will itself conduct the fighting against vital points in the enemy's back areas by means of bombing squadrons and giant aeroplanes which it will bring into action.

A Study of the Vulture and Golden Eagle

(*Continued from page* 89).

WHEN one goes still-hunting for a Tawny Vulture, upon first coming into sight he does not appear to be a large bird. At the altitude at which be habitually soars he appears to be about the same size as the Kites and the Egyptian Vultures—he makes no more impression than they. One learns quickly to distinguish him by the angle to the front produced by his wings, by the absence of wing beats, and above all, by the slowness and steadiness with which he moves in space. This is an infallible sign by which to recognize him as far as the eye can distinguish. It is only later that his true size will be understood, when he is only 100 or 300 yards off. As he approaches within that distance he grows in appearance much faster than the other birds.

He is further distinguished by the peculiar spread of his wing tips. This is the bird who spreads his primary feathers most widely apart. At the extremity there is an open space between each quill equal to about five times the width of the feather.

Still another peculiarity is that the primary feathers, instead of tapering toward the point, are constructed on the reverse plan; they seem to be implanted into the wing by the thin end, the outer tip being materially wider than the part which seems to be attached to the wing and which precedes the main widening of the barbs. These large feathers, widest at their tip and spread asunder, present a curious outline which would please artists greatly if they observed this bird in bis native habitat.

To the peculiar construction described we must add the effects of the partial rotation of the quills within their sockets, which action is observed only in these large birds. The quills must be wonderfully strong and elastic, for the birds put them to severe proof. During the efforts which he makes when starting up from the ground and when his pectoral muscles are doing their utmost, the tips of the feathers point directly to the zenith. In short, from every point of view these great birds are exceedingly interesting to observe when free. There are attitudes quite unknown to those who see the bird only in museums.

But there must be freedom. Otherwise we have only Eagles motionless as milestones, or ill-smelling Vultures apparently worrying themselves to death, their heads smothered between their shoulders, two aspects which have nothing in common with that of these kings of the air proudly traversing the immensity of the skies. One circumstance which frequently deprives the observer of the chance of witnessing their interesting evolutions is the bird's alarm. At the slightest apprehension, these great creatures resort to rowing flight, seeking to get rapidly beyond danger. So, developing all their powers with strokes of wing, they quickly fly away.

Their power of vision must be great; we may safely assume this, because these birds, of all flying creatures, are those whose mode of life requires the most extensive views.

A sparrow needs a field of view of but a hundred yards. A more powerful organ of sight would be needless, and therefore atrophied in a few generations. The sea birds need to observe the surface of the waves for only a dozen yards or so. It is not among these creatures that those perfect lenses are found, capable of collecting all divergent rays of light.

The hunting birds of prey, such for instance as the Falcons and the Eagles, often scrutinize the surface of the ground from a great height. The latter birds sometimes remain at an elevation of 400 or 500 yards while hunting, but what is that distance when compared with the 3 or 4 miles required by the Vultures to study their field of research?

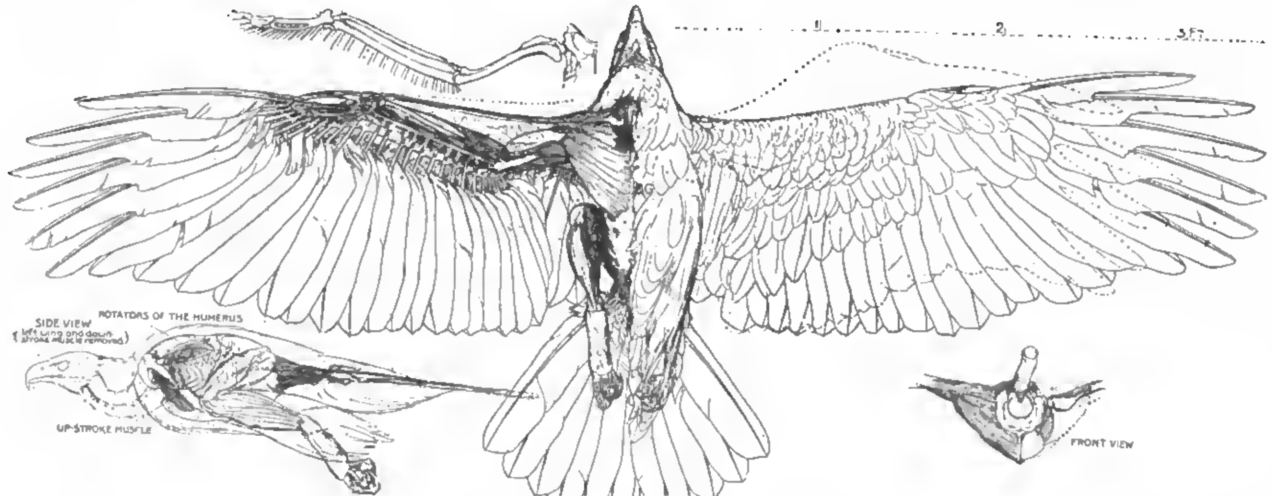
We may safely conclude that the constant necessity for seeing further than other birds has caused them to acquire in the organ of vision a perfection not possessed by other birds. We must therefore render ourselves invisible to them in order to be able to witness their extraordinary evolutions when sailing. Or, better still, we must seek them in the primitive countries where they have not yet learned to be afraid of man, and even there, clothes which shall not attract the attention should be worn, for otherwise they will not come down to a meal.

Unfortunately the Vulture is an unknown bird to those interested in the problem of soaring flight, for comparatively few people have seen him in the air. In Algeria, even in Cairo (where there are some sailing over the city every day during three months of the year) most of the European residents are unaware of their existence. But when the student takes the pains to go where the bird is to be found; when he sees this great animal, large as a sheep, painfully rising from the ground with strokes upon the air whose hissing is heard 300 yards away in the silence of the desert; when he sees them afterwards describing their endless sweeps, he appreciates this most interesting sight—every human being is chained to the spot. Even the Arab is stirred to emotion, for in this bird we have found motion under a new aspect. As to majesty and impressiveness, it resembles the action of a locomotive at full speed.

When we watch a Martin flashing through space we think of high speed mechanism; when it is a snipe or partridge which flies off, we are reminded of the action of a released spring; a gull suggests perpetual motion or the endless sweep of a pendulum, but the view of the great Vulture in sailing flight inspires at once the desire for imitation. It is a dirigible parachute which man may hope to reproduce.

The Great Golden Eagle

Undoubtedly the Eagle is the king of birds. He possesses strength and courage. Having no enemy his equal, he peacefully passes long days in the beatitude of uncontested autocracy. (*To be concluded*)



Anatomy of the Golden Eagle. Weight, 10 pounds. Loading, (wings only), 1.6 pounds per square foot. Wing span, about 6 ft. 10 inches.

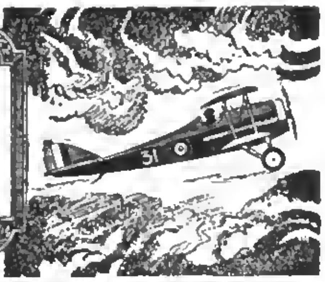
ELEMENTARY AERONAUTICS *and* MODEL NOTES



A Flying Scale Model of the Fokker F III Cantilever Monoplane

FOLLOWING the correct proportions of the Fokker-Cantilever monoplane, Mr. M. J. Bayhi of Hempstead, Long Island has designed and constructed an attractive and efficient 36-inch scale flying model. The outlines have been carefully copied in reduced scale, resulting in one of the finest scale model designs of its class.

In a model of this character, opportunity is afforded to apply some clever workmanship in the wing construction. On account of the deep section required for the cantilever bracing, and because of the absence of external stays or supports, the wing structure is built up in an unusual way. The ordinary wing spars are replaced with light stringers which stiffen the wing and give good support to the ribs.

Measurements are as follows:

Wing span (with balanced ailerons)	38¼"
Length over all	27¾"
Height at wing	9 "
Wing chord, at fuselage	6½"
Wing chord, at tip	4⅜"
Size of landing wheels	2 "
Propeller diameter	12 "

A record was made of the weights of each separate part, accurate to within one-one hundredth (1/100) of an ounce. These weights total up to nearly 9 ounces for the complete model. The wing weight includes the aileron weight also. The fuselage weight includes also the weights of landing gear, tail unit and power unit. Landing gear weight includes wheels. Tail unit comprises the rudder, stabilizer and elevators.

List of Weights:

	Ounces
Model complete and ready for flight	8.96
Wing	2.30
Fuselage complete	6.66
Landing gear	1.32
Tail unit	.21
Propeller	.94
Power plant (not including propeller)	2.22
Rubber power	1.30
Cowls	.48

General Description

Fuselage

Longerons and struts ⅛" square spruce nailed and glued together.

Covering is of bamboo paper, is doped and afterwards painted Fokker style.

Shock absorbing tail skid is used.

Cowls are of sheet aluminum.

Sockets for attaching landing gear to fuselage are light aluminum tubing.

Forward part of fuselage including cowling is painted dark blue. Rear is painted aluminum color.

Empennage

All tail surfaces are constructed of ⅛" x 1/32 spruce and 1/16" diameter reed.

All controls are balanced. Bamboo paper used for covering. Whole empennage is doped and painted aluminum color.

Landing Gear

Small streamline struts are arranged as on the real machine, four struts on each side. Each "W" strut weights .01 ounce.

Wheels are 2" diameter.

Shock absorbers are used. Cross wiring in both front and rear bays.

Attachment to fuselage by means of aluminum sockets.

Propeller and Motor

Propeller 12" diameter mahogany.

36 feet 3/16" flat rubber is used for motive power.

200 turns of propeller flies the model about 100 feet.

Motor stick of ¼" x 5/16" spruce.

A ball bearing propeller shaft is used.

Wing

The wiog section at fuselage is the "Gottingen" No. 387; at tip, "Gottingen" No. 436. Wing tapers both ways. Chord at fuselage, 6.5"; at tip, 4.375". Two center ribs are located over the longerons. They are of ⅛" balsa, lightened. 14 ribs are used. The center rib on each side of the fuselage, between the centerline of the machine and the tip, is of 1/28" Spanish cedar veneer, lightened. The rest are 1/45" Spanish cedar veneer, lightened. The tip rib is faired with Balsa, thusly obtaining a rounded wing tip.

Regular balanced Fokker ailerons are used.

Wing spars are of ⅛" square spruce. Notches are cut in the ribs to receive the spars. Two spars are used; that is, one rear and one front. Both rear and front spars are constructed of two pieces. The total apnel weighs 2.3 ounces. Covered and with ailerons.

Mr. Bayhi has had good opportunities for studying the Fokker machines demonstrated by the Netherlands Aircraft Company. These machines make frequent flights at the Curtiss flying field near Mineola. Mr. Bayhi has made trips as a passenger with Bert Acosta, giving him an intimate knowledge of the flying qualities of the Fokker F III.

A later issue of AERIAL AGE will contain a photograph of this model in flight, showing its remarkable resemblance to the real Fokker monoplane.

Extensive flying tests have not been made of this model, but in the preliminary demonstrations the performance proved its correct design and balance. The propeller was given only 200 turns, and with this power the model took off the ground in a run of about five or six feet, quickly rose to a height of about six feet, descending gracefully in a glide to a point 100 feet from the starting place. The horizontal speed of the model was judged to be rather high, and later tests are to be made in an effort to increase the distance and duration flown by (1) reducing the quantity of elastic motive power, (making more possible revolutions of the propeller); (2) setting the wing at an incidence angle of one degree; (to obtain more lift) and (3) replacing the present propeller by ooe designed with a view to less speed and more efficient thrust. A later issue of AERIAL AGE will contain a photographic illustration of the model in flight, showing the remarkable resemblance to the real Fokker monoplane.

The Aeronautis

She was shaped like a huge cigar,
  Five thousand feet long her keel,
She was built of light metal,
  Stronger than the toughest steel.
  * * *
Her diameter in the center,
  Was three hundred feet through.
Tapered to almost naught at ends.
  Only ninety was her crew.
  * * *
Her windows were made of malleable glass,
  Clear as crystal one inch thick.
She had large libraries & lecture halls,
  And a large hospital for the sick.
  * * *
Slowly the monster airship rose,
  To circle the earth in a day.
At a mile from earth she stood still,
  In the busy aerial way.
  * * *
For an hour we lay up there,
  To take more passengers aboard.
They came to a floating dock,
  By air in a veritable horde.
  * * *
This huge floating dock of the air,
  Now stood by our side.
When we had all her passengers,
  Slowly away it did glide.
  * * *
Thousands of airships passed us by,
  Some were large and others small.
There were business and pleasure ships,
  Some shot fast and some did crawl.
  * * *
The huge doors were now all closed,
  We shot straight up in space.
The ship was now airtight all round,
  The crew all in their place.
  * * *
At fifty miles from the earth,
  We first traveled forward.
At a thousand miles per hour,
  The huge ship gracefully soared.
  * * *
We scarce knew we sailed at all,
  Fifty miles from the earth.
The salons and spacious ball rooms.
  Were ringing with music and mirth.
  * * *
There was no roar of whirling props,
  There were no props or engines beat.
There was no grind of huge machines,
  To give the monster ship her speed.
  * * *
Of oxygen there was plenty,
  Twas stored in bins like salt.
Apparatus turned it hack to air,
  As need arose without a fault.
  * * *
With fine solar instruments,
  Heat vibrations from the sun
Were taken direct from the ether.
  And kept all from the cold undone.
  * * *
We seen huge freighters of the air,
  Glide swiftly past our view.
Controlled completely from the earth,
  Without a soul aboard they flew.
  * * *
The crew knew through instruments,
  When another ship drew near.
Automatically ships were kept apart,
  All ships of ships always ran clear.
  * * *
At night the glitterings in the sky,
  Were the most glorious sights.
Not seen from earth in their grandeur,
  Were the playing northern lights.
  * * *
Most people flew for health and pleasure,
  Around the world in this great girth.
By wireless always kept aware,
  Of all doings on the earth.
  * * *
The ship was run by vibrators,
  Sending out vibrations together.
Which were repelled by opposites,
  Thus driving the ship through the ether.
  * * *
Thus also was the huge ship raised,
  Lowered or turned about at will.
Going backward as well forward,
  Or in midair stand stock still.
  * * *
Through what looked like glowing bulbs,
  These vibrations were outward sent.
From nine above and nine below,
  Nine on each side one at each end.
  * * *
The wise with the low brows said,
  What a fool's imagination.
'T is all a dream a wild-eyed dream,
  Impossible of creation.
  * * *
As 'twas said of the steamboat,
  Wireless and the modern aeroplanes.
The grafaphone and automobile,
  Electric lights, locomotives and trains.

H. Theo. Haller

The Seaplane

Ye earth-bound mortals, frail and weak,
Be still and hear the Seaplane speak:

"A fair, young god just born, am I,
And I cleave the heavens as eagles fly;
My gray sides shimmer in the sun,
My taut wires sing as the race we run.
Upward, yet higher and higher I spring,
Swift as swallow with lightning wing,
Straight to the face of God.

The sea-gull swerves to give me room
And screams aloud as he hears the boom
And roar and hum of my mighty heart,
As hither and yon in the clouds I dart,
Playing "I-Spy" with the sun's bright beam
That wraps me round in a golden sheen—
A shield from the earthly sod.

I dip, I rise like the waves of the sea,
The mother whose bosom has nurtured me.
And ever and ever I feel a thrill
Of joy as I go at my master's will.
The winds beat against my golden wings;
As I dash in their teeth my soul it sings,
And I turn, and I twist, and I roll.

I scorn those weaklings caged on earth,
Of mortal soul and mortal birth;
Above, I soar, in realms sublime.
Kissed at birth by gods divine,
A god I live, a god I'll die,
For I fly to live and live to fly.
A Seaplane, I, with a god's young soul."

Julia Baker.

A Ham Joke

He—I live in my Mary's eyes.
Him—Yes, I noticed she had a sty in them.—*Lord Jeff.*

STATEMENT OF THE OWNERSHIP, MANAGEMENT, CIRCULATION, ETC.,

REQUIRED BY THE ACT OF CONGRESS OF AUGUST 24, 1912,

Of AERIAL AGE WEEKLY, published WEEKLY at NEW YORK, N. Y., for APRIL 1, 1922.

STATE OF NEW YORK }
COUNTY OF NEW YORK } ss.

Before me, a NOTARY PUBLIC in and for the State and county aforesaid, personally appeared G. DOUGLAS WARDROP, who, having been duly sworn according to law, deposes and says that he is the EDITOR of the AERIAL AGE WEEKLY and that the following is, to the best of his knowledge and belief, a true statement of the ownership, management (and if a daily paper, the circulation), etc., of the aforesaid publication for the date shown in the above caption, required by the Act of August 24, 1912, embodied in section 443, Postal Laws and Regulations, printed on the reverse of this form, to wit:

1. That the names and addresses of the publisher, editor, managing editor, and business managers, are:

Name of—	*Post office address*
Publisher, AERIAL AGE CO., INC.	5942 Grand Central Terminal, N. Y. C.
Editor, G. DOUGLAS WARDROP	5942 Grand Central Terminal, N. Y. C.
Managing Editor, none	
Business Manager, G. DOUGLAS WARDROP	5942 Grand Central Terminal, N. Y. C.

2. That the owners are: (Give names and addresses of individual owners, or, if a corporation, give its name and the names and addresses of stockholders owning or holding 1 per cent or more of the total amount of stock.)

AERIAL AGE CO., INC. ....5942 Grand Central Terminal, New York
G. DOUGLAS WARDROP....................5942 Grand Central Terminal, New York

3. That the known bondholders, mortgagees, and other security holders owning or holding 1 per cent or more of total amount of bonds, mortgages, or other securities are: (If there are none, so state.)

NONE.

4. That the two paragraphs next above, giving the names of the owners, stockholders, and security holders, if any, contain not only the list of stockholders and security holders as they appear upon the books of the company but also, in cases where the stockholder or security holder appears upon the books of the company as trustee or in any other fiduciary relation, the name of the person or corporation for whom such trustee is acting, is given; also that the said two paragraphs contain statements embracing affiant's full knowledge and belief as to the circumstances and conditions under which stockholders and security holders who do not appear upon the books of the company as trustees, hold stock and securities in a capacity other than that of a bona fide owner; and this affiant has no reason to believe that any other person, association or corporation has any interest direct or indirect in the said stock, bonds, or other securities than as so stated by him.

5. That the average number of copies of each issue of this publication sold or distributed, through the mails or otherwise, to paid subscribers during the six months preceding the date shown above is ....
(This information is required from daily publications only.)

G. DOUGLAS WARDROP,
Editor.

Sworn to and subscribed before me this 31st day of March, 1922.

DANIEL F. NUGENT,

Notary Public, Queens Co., 1721; Certificate Filed in N. Y. Co., 27.
[SEAL]
(My commission expires March 30, 1923.)

Form 3526-Ed. 1916.

NOTE.—This statement must be made in duplicate and both copies delivered by the publisher to the postmaster, who shall send one copy to the Third Assistant Postmaster General (Division of Classification), Washington, D. C., and retain the other in the files of the post office. The publisher must publish a copy of this statement in the second issue printed next after its filing. c5—6012

Learn *to* Fly

Aviation is making such strides that it needs more men right now

You Can Learn To Fly

I can teach you how to become a successful pilot in a short time. My course is so arranged that you get only the things you need to make you a good aviator.

The Diggins Extension Course

is up-to-date, teaches you what you must know to become an expert flyer. This course is written by competent instructors right on my flying field. It is kept right up to the minute—all new developments in aviation are included. That is why it is recognized as the most complete and practical course offered today. My course saves you time and money because it prepares you at home so that you are ready to begin flying the day you arrive at the flying school.

Superior Points of the Diggins School

1. The Diggins school is the oldest, largest and most complete commercial aviation school in America.
2. The Diggins school is located in Chicago, the center of Aviation.
3. Living quarters and free employment service are maintained for students.
4. Diggins guarantees to make you a pilot.
5. Diggins' pilots get top notch salaries.
6. References, any aero club in America.

WRITE TODAY Write today for the new Diggins beautifully illustrated catalog.

An Air Force Academy Suggested

CREATION of a United States Aeronautical Academy, to be to the air service what West Point is to the army and Annapolis to the navy, is contemplated in a resolution introduced April 3rd by Senator Walsh of Massachusetts. The resolution directs the Secretaries of War and the Navy to investigate and report to Congress on the advisability of establishing such institution.

"Immediate and adequate development of the science of aeronautics," said Mr. Walsh, "is vital to the protection and prosperity of the country. Aviation is now recognized as a dominant factor in relation to future transportation as well as to the national defense. It is a matter we cannot permit to sleep.

"As the Conference for the Limitation of Armament took no action to reduce, limit or control aviation, so far as its use in war is concerned, it should be apparent to the most casual observer that a sufficient and properly trained personnel, capable of developing, instructing and directing the aviation activities of the nation is important.

"If this country is not to be outdistanced in the field of aeronautics and thereby left defenseless, a separate school of aeronautics supported and controlled by the Government should be established."

Senator Walsh suggested that a part of West Point or of Annapolis or some navy yard be used for the Academy.

It is to be hoped that Senator Walsh's suggestion will have the attention which it merits.

A Saga by Wireless

IN their little skiffs the Norse vikings roamed the polar seas, and Scandinavian bards related their exploits in sagas. That was the style of reporting in those days. Now Roald Amundsen, twentieth century viking, equally at home in the cellar and on the roof of the world, expects to float to the North Pole in the good ship Maud, with casual side hops in a metal aeroplane, and he will send daily bulletins of all the Arctic news by radio. Sagas by wireless! It's the modern way.

Most polar expeditions are described as "dashes." Amundsen's trip will be more leisurely. The ice pack on which he is to drift has much to learn about rapid transit. Its timetable promises to deliver the explorer at the pole in three or may be five years. Yet he says there is enough of interest in the million square miles of uncharted surface to keep the ten members of the expedition busy every waking moment. He has high hopes of enriching the store of scientific knowledge and in particular of solving the mystery of the aurora borealis.

Of major interest in the enterprise is the auxiliary use of the aeroplane. It will be the first real test of the feasibility of aerial reconnoissance in the Arctic regions.

—Editorial in N. Y. Tribune.

Aviation—First Line in War

AVIATION has taken a sudden jump to the front as a recognized and invaluable agency in war. When the British government, which has always, and very rightly, in the past considered its navy as the first line of national defense voluntarily renounces this theory and admits that the conditions in 1922 have forced the conclusion that air forces have displaced both the army and navy as the dominating element in the protection of the British Empire we may well take notice—conservatism in the United States must awake from its stupor, and permit intelligence to control our military and naval policies.

Admiral Fisher and Sir Percy Scott, of the British navy, long ago foretold the reign of air power in war, but their warnings were little heeded by the controlling minds in the House of Commons until recently, when Austen Chamberlain raised the question in debate as to "what extent developments in aviation may render naval warfare more obsolete."

Mr. Chamberlain said "he could imagine circumstances might soon lead the world to believe that limitation of battleships or armaments would be of little use unless similar limitation was placed on air craft. . . . Believing as the government did, that the air force had immense potentialities, quite distinct from its duties as an adjunct to the naval and military service, and convinced that in the future the greatest danger to Great Britain might well be from an action by air forces, the government considered it would be a retrograde step to abolish the air ministry and reabsorb the air force into the Admiralty and War Office."

In conclusion Mr. Chamberlain declared: "In case of air raids the army and navy must play a secondary role, but in case of military or naval operations the air force must be in strict subordination to the general or admiral in supreme command."

These astonishing admissions on the part of the British government are justified—in fact, their soundness is conclusively demonstrated by recent happenings. It will be recalled that the Spaniards have used bombing planes to dislodge and demoralize the Moors when other weapons failed, thus saving their battalions from decimation by frontal attacks against a determined enemy. General Smuts employed bombing planes with similar effect against the rebels in South Africa, who were quite unprepared and helpless against this form of attack.

And now we are informed that "the possibility of effectively controlling a troublous country by means of an 'air army' is to be thoroughly tried out by the British in Mesopotamia."

Winston Churchill has taken the lead in this enterprise. "A fleet of 150 troop-carrying planes is under construction, each capable of carrying ten soldiers fully equipped, together with two machine guns and ammunition. By this means a complete battalion of 1,000 men can be transported hundreds of

THE NEWS OF THE WEEK

U. S. S. Langley Commissioned as Airplane Carrier

Norfolk, Va.—The U. S. S. Langley, airplane carrier, has been commissioned at the Norfolk Navy Yard. The ship was turned over to the Navy by the Navy Yard, and Commander Kenneth Whiting has assumed command of the vessel until her commander shall have been appointed. Commander Whiting will remain on board the ship as executive officer at all times, however.

Commander G. de C. Chevalier, U. S. N., will be given complete charge over all aviation activities aboard the vessel. He will come under the captain and executive officers, but he will have entire command of all the movements of the aviators and their craft, on the ship.

The commissioning of the ship was ceremonious, since the *Langley* is the first of her kind to be commissioned in the United States Navy.

Several hundred men, including architects and mechanics of nearly all the trades, have been employed in making the former collier *Jupiter* a complete airplane station afloat. Incident to her being a "harbor" for aircraft, the*Langley* will be one of the most peculiar looking ships on the seas. The thing in her build, which makes her radically different from other ships, is her landing deck. That deck is an immense platform, mounted above her main deck on trussed towers. Only by standing on that great platform can its proportions be appreciated. One is impressed with the feeling of standing on a field, so large is the deck.

Deep down in her hold has been stored quantities of chain and concrete, which will serve as ballast. Above this invaluable "cargo" and in the forward part of the vessel will be installed a complete shop for the repair of all kinds of aircraft. With the proposed machinery in her hold, and a capable crew, it will be possible to construct a plane almost completely aboard the vessel.

The *Langley* is 525 feet long and 65 feet beam, and she is driven by motors with a total horsepower of 5,500. She is said to attain a speed of 14 knots. The ship was built at Mare Island Navy Yard in 1912. Later, when the value of a ship of the type she now is was realized, the Navy Department turned the vessel, then a collier, over to the Navy Yard here, where she has undergone building changes for two years. The ship, although commissioned, is not completed. More months must elapse before she can steam out on her trial trip.

During the World War, aviation made a remarkable advance. In naval circles especially has the value of aircraft been realized. A home had to be provided for the "wasps," and it fell to the lot of the *Jupiter* to be converted.

Her name was changed to honor a pioneer of aviation, Langley, the man who was laughed to ridicule and whom Congress refused to grant money for the perfection of his airplane models because they were "impractical." He is now to be immortalized by a ship on the seas.

The ship is not quite completed. Before she will be ready for service her equipment must be installed. That one word "equipment" will include the only complete aviation repair and construction shop afloat.

Other additions to the strange vessel will be made in due time and all work is expected to be completed by May 1.

Flying Club of St. Louis

The Flying Club of St. Louis has established a flying field and club house eight miles from the city limits on the Natural Bridge Road. This field is northwest of St. Louis and situated on the Wabash Railroad at Anglum, Mo. It can be distinguished from the air principally by the hangar and a large grain elevator. No charge is made for the use of the field and space for hangars is provided free of charge.

The club is planning to organize a reserve unit for both lighter and heavier than air, and will cooperate with Scott Field, where at present the Air Service is constructing a large steel hangar for dirigibles.

The Advisory Board of the Flying Club is as follows: Albert B. Lambert, Chairman; Sam D. Capen, L. D. Dozier, F. W. A. Vesper, Ed. T. Hall, Frank C. Rand, Fred H. Semple, Col. A. T. Perkins, Harry B. Wallace, Robt. T. Morton, James M. Hranciscus, W. C. D'Arcy, Jesse McDonald, Geo. P. Dorris, M. W. Hayes.

Personal Par

M. A. C. Johnson, of Akron and Troy C. Williams, of Augusta, are barnstorming Georgia, North and South Carolina in a Standard-Curtiss.

W. B. A. C. Progress

The World's Board of Aeronautical Commissioners is making rapid strides in its membership campaign in the United States. There are 1937 nominated for membership, 2884 counties out of 3048 are represented by acceptances of state nominees, and 8088 cities and towns represented by acceptances of county nominees. Ninety-four countries and colonies are now represented by 111 commissioners.

Plan Airship Service England to Australia

London—A proposal for the formation of a company with a capital of £4,000,000 to start a mail and passenger airship service between England, India and Australia has been laid before the Government.

A powerful financial syndicate has offered to take over the British airship fleet which was due to be consigned to the Disposal Board. No capital investment by the Government is required, but there is a contingent liability in the form of a guarantee of interest and dividends of £91,000 a year from the State.

Messrs, Vickers, Limited have undertaken to subscribe for 100,000 shares at par and the Shell groups for 100,000 ordinary shares or debentures at par. Both companies will give full technical assistance.

The total contingent yearly subsidy in the form of a guarantee of a dividend on the ordinary shares and interest on the debentures (on the capital now proposed to be issued) would be on £1,200,000 ordinary shares, £72,000 for ten years. On £2,200,000 debentures, £990,000 until redemption. Dividing the subsidy among the countries which would obtain the benefit of airship service the cost would be: Britain, £91,000 a year; Australia, £40,000 a year, and India, £40,000 a year. These dividend and interest payments would cease as soon as profits from the company were sufficient to pay them.

The program of development has been divided into two stages—a bi-weekly service to India and an alternate day service to India with weekly extension to Australia.

The Government is asked to transfer to the company free of cost all airships, airship material and airship bases and supply wireless telegraphy and meteorological services.

If the scheme is approved, it is claimed the airship passengers from England would reach Bombay in five and a half days, Rangoon in seven and a half days, Hongkong in eight and a half days and Australia in eleven and a half days.

The new ships will be capable of carrying a hundred passengers and eight to ten tons of mail, and will have a cruising speed of sixty miles an hour.

Attacks Navy Air Exams.

Washington—Senator Walsh told the Senate Naval Affairs Committee on April 6 that "unjust examinations" are driving 500 Naval Reserve airmen, among them some of the best in the service, back into private life. The Massachusetts Senator suggested that the committee ask the Navy Department to correct what he described as "a deplorable situation." Some of the most efficient and experienced air officers were being forced out, the Senator said, by "trick" examinations.

"These men are trained in the science of aviation over a period of years and then called upon to pass examinations involving navigation, steam engineering and other subjects with which they, in the very nature of their work, are not familiar," the Senator continued.

"I will show that there is discrimination in the navy between the boy from the ranks who wins his commission through hard work and on his merits and the boy who goes through Annapolis. The aviation arm is one that cannot be trifled with in any efficiently organized modern navy."

Efforts of certain old-time officers who, he said, were opposed to the naval aviation program were another handicap to proper development of navy aviation, said Senator Walsh.

COMING AERONAUTICAL EVENTS

AMERICAN

Apr. 30.	—Spring Show and Opening Meet, Curtiss Field, Mineola, L. I.
May	—National Balloon Race.
Sept. 4. (*about*)	—Detroit Aerial Water Derby, Detroit. (Curtiss Marine Flying Trophy Competition.)
Sept. 15. (*about*)	—Detroit Aerial Derby, Detroit. (Pulitzer Trophy Race.)
Sept. 30.	—First Annual Interservice Championship Meet. (In preparation.)

FOREIGN

Aug. 1. (*about*)	—Coupe Jacques Schneider. (Seaplane speed race.) Italy, probably Venice.
Aug. 6.	—Gordon Bennett Balloon Race, Geneva, Switzerland.
Oct. 1.	—Coupe Henri Deutsch de la Meurthe. (Aeroplane speed race.) France. American elimination trials, if required, to be held about Aug. 15, at Mitchel Field, L. I.

Detroit-Cleveland Airline

Eddie Stinson, holder of the world's endurance record, who recently purchased a number of Junkers monoplanes from the Government, is now in Detroit having the machines overhauled at the Stout Engineering Laboratories, and when the changes have been completed a line will be established between Detroit and Cleveland. It is planned to make eight trips a day.

Stinson is having one machine especially equipped for long distance work, and this summer he will attempt a non-stop flight from San Francisco to New York, and he is thoroughly confident he will be successful. Stinson is one of the most experiences fliers in America, and his many friends throughout the country are congratulating him on his new enterprise and wishing for him the utmost success.

Curtiss Employees Fly to Keep in Practice

Through the efforts of Mr. Theodore Wright, Executive Engineer of the Curtiss Aeroplane and Motor Corporation at Garden City, employees of the company who were formerly pilots, are allowed the use of a JN aeroplane for practice flights. Mr. Wright, who was a naval flying officer, and several other members of the engineering department formerly in the flying service, are able to keep up their practice by this arrangement with the Curtiss officials.

Pilot C. S (Casey) Jones is supervisor of flights, which are now made on Saturday afternoons, Sundays and holidays, but with the coming of "daylight saving" time, opportunity will be had for flights in the early evening. At present, the pilots now elegible for practice flying are: Theodore Wrigbt, C. A. Koch, S. Joseph, E. E. Tatersfield, V. Higbie and John H. De Mott. Mr. H. Ogden, employed in the engineering department, is progressing rapidly in the art of flying, under the instruction of "Casey" Jones.

The Curtiss Company recognizes the value of trained flyers in its organization and encourages their work in a practical manner.

Personal Par

Mr. Grover C. Loening, President of the Loening Aeronautical Engineering Corporation was recently operated on for appendicitis at the Knickerbocker Hospital by Doctor D. W. Martin, Chief Surgeon of St. Luke's Hospital.

The attack was very sudden, but the operation was entirely successful. Mr. Loening has now left the hospital and is expected to be back at his work in a week or ten days.

Wallace Field News

A busy season is looked for at Wallace Field. An innovation there this year will be an Airplane Filling Station, where filtered high test gas will be supplied to flyers from a ten-barrel underground tank, with pump rigged high enough for its 16-foot hose to reach the gas tanks of any ships and fill them almost instantaneously.

J. Wesley Smith has joined Frank Wallace's corps of flyers, and companies operating from the field will include:

The Carlson Aviation Company.

The Aircraft Service and Sales Company.

The Fred Brown Repair Company.

Wallace Field is registered, contains 103 acres, and is open to the use of all flyers. It is located on the Mississippi, just above Davenport—a "town with eyes on the top of its head."

AERONAUTIC CHARTS

By STORY B. LADD

THE chart is for the guidance of aviators, so that an operator can lay his course direct for his objective point and can, en route, check and correct his course for air drift.

The underlying principal is the subdivision of the continental areas into blocks, and the installation of markers at the intersection of block lines which, by reason of their shape, contour, or distinguisbing features, as viewed from above, will indicate to the observer the geographic position of the market.

It is not proposed to post the entire country, nor any portion thereof, by the installation of markers at all points, but to provide a system which can be added to or differentiated as the growth of air travel requires, and whenever or wherever a marker is installed, whether under national or state auspices, by Aero Clubs, Chambers of Commerce, or other organizations, it will be in harmony with the general plan, and become a part of the continental system.

The blocks are spherical quadrilaterals, laid out on lines of latitude and longitude, and the term as here used refers to an area bounded on the east and west by north and south lines, and on the north and south by east and west lines; by meridians of longitude and parallels of latitude, respectively.

The term "marker" refers to a device or structure, preferably erected so as to stand above other objects in the neighborbood and be distinguishable at a distance.

It is important that the system, in its growth and development, be continental in its scope, without breaks at national or state bounderies, and that all markers, wherever installed, shall be alike in character and significance, and speak the same language to the aviator. In this presentation it is described as applicable to a world system.

Eight degrees, of longitude and latitude, has been taken for the major blocks, these to be subdivided into quarter sections, and the quarter sections into quarter blocks, giving, as a result, 16 quadrilaterals, 2° by 2°, these being referred to as intermediate blocks. These intermediate blocks are in like manner subdivided into quadrilaterals of 24' by 24' making 25 subdivisions. These are the minor block units, and each marker that is installed identifies a minor block.

With major blocks of 8° standard for all countries, the major blocks in the equatorial zone will be approximately 550 miles square with intermediates (2°x2°) of 138 miles, and minor blocks (24'x24') of 27.6 miles. Going north and south from the equator, the distances along meridional lines will be constant, witb the distances along parallels of latitude gradually diminishing. At the 40th parallel, the east and west dimension for the major blocks will be approximately 428 miles; for intermediates, 107 miles; and for minor blocks, 21.4 miles. At the 50th parallel of latitude, these distances will be approximately 360 miles, 90 miles, and 18 miles, respectively: and at 60°, 280 miles, 70 miles, and 14 miles.

The subdivisions of the intermediate blocks may be 36 in number, 6 in a tier, each 20'x20', or even 64 in number, 8 in a tier, each 15'x15', if the markers on the basis here outlined are too far apart, but it is thought provision for shorter intervals, when desirable, can be best met by midblock markers at half intervals.

For purposes of identification, the intermediate blocks are lettered *A* to *P*, beginning at the northwest corner of a major block and in quarter section groups, the letters *A*, *B*, *C*, and *D* indicating the four intermediate blocks of the northwest quarter section; *E*, *F*, *G*, and *H* those of the northeast quarter section; *I*, *J*, *K*, and *L* the southwest quarter section; and *M*, *N*, *O*, and *P* the southeast.

The major blocks are to be cited by the longitude and latitude of the northwest corner of the block, and as all major blocks are 8° in dimensions these numbers are always multiples of 8, longitude being placed first. Thus "104-48" identifies a block bounded by meridans 98° and 104° (in the western hemisphere) and by parallels of lattitude 40° and 48° (in the nortbern hemisphere); and "104-32" identifies the major block covering southern Texas and a portion of Mexico. If there is any question as to the quarter of the globe, designating letters will precede the numbers. In tbis event, the above noted blocks will be designated "N. W. 104-48" and "N. W. 104-32." "N. E. 40-48" is a block covering parts of Southern Rnssia and tbe Caucasus; "S. E. 16-24" (still using the northwest corner for blocks in the southern hemisphere) the Soutb African Union; and "S. W. 64-32" portions of Argentina and Uruguay.

The letter designation of the intermediate block follows the major block designation—thus "N. W. 104-48 C" indicates the intermediate block *C* in a major block, the northwest corner of which is 104° west longitude, and 48° north latitude.

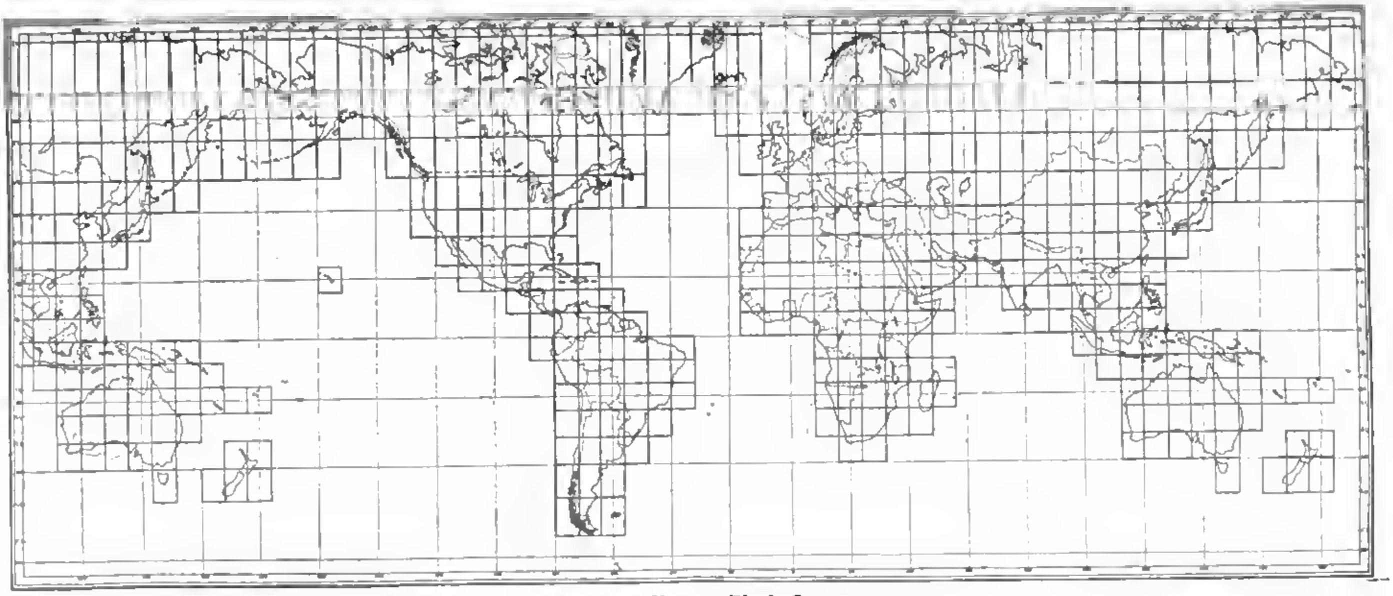
The minor blocks are identified by numbers 1 to 25, beginning at the northwest corner of the intermediate block. These are the marker numbers. In designating a minor block, the number follows the intermediate block letter, thus "104-48 C 10" identifies a specific location (the marker may or may not have been installed) in block "104-48 C."

Markers.—The markers are platform structures, carried by skeleton towers, high enough to clear surrounding objects, and in forest and timbered districts to show above the trees. In open country an elevation sufficient to be out of the way of cattle and drifting snows will suffice.

In mountain or broken country where the true location of a marker comes in a ravine or valley, or where it would not be visible from a distance, it will be located at the nearest available point, the offset showing on the charts.

The contour of the platform is the dis-

1) See "Aerial Age", of Aug. 22, t92t and Dec. 26, t92t.



Aeronautic Charts—Block System

Digitized by Google

tinctive feature of a marker that identifies the intermediate block in which it is located, and it is desirable that the distinctive shapes be as few and simple as possible. To this end the shapes recommended are four in number, circular, square, triangular, and a trefoil. In this connection, the effect of foreshortening is to be borne in mind, a circle appearing as an ellipse and a square as a diamond or a rectangle. All markers within an intermediate block are to be of the same contour. The shape of the platform as viewed from above identifies the intermediate block, and the four shapes suffice for the four intermediates that form a quarter section of a major block.

It is necessary that the visibility of the markers be preserved under snow conditions when the ground and the platforms are white with snow. For this purpose the platforms are made with a skirt around the outer rim, sloping outward at a steep angle and painted black. From above this rim skirt will appear as a black line outlining the edge of the marker. Snow may adhere thereto to some extent on the windward side, after a storm, but sufficient portions will be exposed to catch the eye of the aviator.

The quarter section is preferably to be indicated by an adjumct that will not confuse the platform contour, but which can be readily interpreted, and in a prior presentation of the project the markets were to be provided with an arm projecting to the northwest, the northeast, the southwest or the southeast, as the case might be. An arm extending out from the rim of the marker will detract from the distinctiveness of the contour and may be confusing to the observer, and moreover he might be in doubt as to the compass direction in which the arm was pointing. It is therefore proposed that the quarter section be indicated by one or more discs, separate and detached from the marker platform, but carried by the platform structure on a level with the platform. The position of these discs with respect to the platform is not material; but for uniformity and in order than an aviator may know where to look for them, they are on the south side of the platform. They may be truncated cones, with black slopes, far enough removed from the platform so that under snow conditions the space between a disc and the platform will not be bridged by the snow and the outline of the platform broken. One disc will signify the first or northwest quarter of the major block, two discs the second or northeast quarter, three the southwest quarter, and four the southeast quarter. The scheme may provide for one, two, or three discs, for the second, third, and fourth quarters respectively, the absence of a disc signifying the first quarter. In the event, however, of an aviator not noting the presence of a disc or discs, he would interpret the marker as being in the first quarter; whereas if all markers carry a disc or discs, he will always look therefor and will not miss the correct interpretation.

The combination of the four contours and the discs provides for tbe ready identification of any one of the 16 intermediate blocks without recourse on the part of the observer to compass directions.

With respect to the major blocks, which represent areas of 200,000 to 300,000 square miles, it is assumed that no marker feature is necessary. An aviator will know his position as between eastern Massachusetts or Ohio, Central Illinois or southern Alabama, the north of France or Spain. With knowledge of the marker shape and the number of accompanying discs, which will appear as dots or spots contiguous to the platform, he at once knows bis position within 2 degrees.

The minor block units are indicated by numbers from 1 to 25, showing in the center of the markers. The number is placed to be read from the south and appears separate and detached from the surrounding platform in the middle of an open central field. The space between the number and the edge of the surrounding platform will be sufficient, in northern districts, to bar the formation of a snow bridge. To maintain the visibility of the numbers under snow conditions, they can be made of hipped lines of steep slopes, and painted black. Though in winter, in some districts, a marker may carry a heavy snow blanket, there will be open space around the number and the lines will be sufficiently exposed to be decipherable. An aviator may not be able to read the number from a considerable elevation or distance, but if knowledge of the intermediate block from the marker contour is not sufficient, he will approach near enough to decipher the number.

At the distances between markers called for by the foregoing, an aviator, when following a posted route, will pass beyond view of a rear marker before he catches a glimpse of the one ahead. Under normal conditions a marker can probably be seen at a distance of 5 or 6 miles. But he will come within view of the forward marker before he can have materially deviated from his course. In a cross flight, however, he may cross a posted line at a midway point and out of sight of a marker. It may therefore be desirable to install markers at such intervals that in a cross flight a marker will be within range of view regardless of where the poster route is crossed. It is proposed to meet this requirement when necessary, by intermediate markers located on the line midway of the minor block corners. They can carry the distinguishing features of contour and disc or discs, called for by the block, and if more exact information is desirable the number with the addition of a short "dash" after the number within the central open field, if the marker is on an east and west line, or below the number, within the central open field, if the marker is on a north and south line. Thus twelve will signify that the marker is located at a half-way point between locations "12" and "13" of the intermediate block, and twelve that the marker is located at a half-way point between locations "12" and "17" of the intermediate block—"7" being the minor block south of "12." It will probably, however, be sufficient for the marker to show only the block contour, for if more exact information is desired tbe aviator will turn aside and look for the next marker on the line.

Inside markers. A marker located within the confines of a minor block, for example in proximity to a landing field, can show the indicia called for by that minor block with the addition of an inside ring around the number and a narrow annular open space between the ring and the platform. This will signify that the marker is within the area of the block, the position of same being shown on the chart for that district.

Frontiers. At the frontier crossing on a postal route, the boundary line can be marked by a split platform of the contour called for by the intermediate block but without the number, the platform being divided by a central gap conforming in direction to the boundary line.

Notice of installations. As installations are made, the locations will be published as items of general news and the aviators will mark the locations on their charts. This publication will call simply for the longitude and latitude designations of the major block, tbe intermediate block letter, and the minor block number. In the case of a marker that is off the true location, its position will be given by coordinates with respect to the block corner; as, for example, when because of the topography of the country, "104-40 D 8" is erected "2 miles north and 3 miles east" of the northwest corner of said clock.

Duplicate markers. If a continental route is posted on an unbroken east and west, or north and south line, there will be a duplication of the markers in the major blocks traversed. For example, if a due east and west transcontinental line is posted from Georgia to California, the series of markers in blocks "80-40," "88-40," "96-40," "104-40," "120-40," and "128-40" will be duplications. This can be avoided, in laying out the line, by offsets between major blocks. If at the junction of "80-40" and "88-40" the line is sidestepped to the next tier of minor blocks, say to the north, it will strike a different series of marker numbers. Then crossing to "96-40" let there be another offset and likewise with each successive block. There will then be no duplications on the entire route. The same course can be followed with respect to north and south posted lines.

Urban and Industrial Districts. A cordon of markers surrounding an industrial district will give an aviator his bearings from whatever direction he approaches. Knowing the longitude and latitude of a point within a district, the block locations, and the proper contour, quarter-section designation and numbers are readily determinable.

Direct routes. The posting of direct routes between points can readily be done in the initiation of the project by installing the markers along the lines of travel at the points called for by the system. Many of these will be at varying distances to the right or left of the line but within view, and where the line of travel crosses a block line at a point some distance removed from a block corner, a midline marker can be installed, as above indicated.

Night travel. For night service on a route where there is regular travel, the markers will be equipped with lights under radio control so that an aircraft, with radio control can, at will, cut in the lights within range, and lights will be on only as needed.

SEVENTH CORPS AREA COMMERCIAL AERONAUTICAL ASSOCIATION ORGANIZED

By R. TAYLOR

Special Correspondent of the Aerial Age

THE Commercial Aeronautical Association of the Seventh Army Corps Area, the first of its kind in the United States, was organized by business men of the area and others interested in aviation at the canvention in Sioux City, Ia., March 27, 28 and 29. This marks the first organized effort in America toward establishment of a commercial air transportation system, and will be followed by similar action in the other eight corps areas, the intention being to ultimately inaugurate a transcontinental air system.

The constitution of the new organization includes provisions for the development of aeronautics both commercially and scientifically; establishment of uniform landing fields in the fifty-nine leading cities of the area; co-operation with other corps areas in promoting a transcontinental system, and cooperation with the war and navy departments in the matter of aerial defense.

The seventh area organization will seek to become a part of the Aeronautical Association of the United States of America, following perfection of the national association at the convention in Detroit in September.

Support of the air mail service and the early passage of the Wadsworth-Hicks bill was advocated in resolutions passed by the convention.

All cities and towns of the Seventh army corps area, which includes Arkansas, Missouri, Nebraska, Iowa, North Dakota, South Dakota, Minnesota and Kansas, will be invited to become members through their aeronautical clubs or chambers of commerce, according to the tentative agreements made at the convention. The corps area organization also will accept personal memberships at $5 each. Local organizations must have not fewer than 25 persons in order to gain admittance to the association.

Cities of 10,000 or under would be represented by one vote in the corps organization, and one delegate for each additional 10,000 of population would be added, according to plans of the officers.

It is planned to divide the cities into three classes. First class cities will be those of 50,000 or more in population; second class, between 12,000 and 50,000, and third class, 12,000 or under.

Requirements of first class cities include possession of a first class landing field; hangar facilities for at least six commercial air craft; repair hangars to care for two planes at a time; oil and gas filling stations; identification markers complying with international rules; a field superintendent on duty at all times, and the location of the field to be convenient for surface transportation.

Cities of class two would need hangar facilities for three ships; emergency repair shops; gas and oil supplies; identification markers; wind zones, and telephone and wireless equipment. Cities of the third class would be known as an emergency landing place, and would be required to have a field, the size and type of which would change according to service required.

Assisting the Seventh district delegates in the organization scheme were Rear Admiral W. F. Fullam, former commander of the naval air forces, and Brigadier General W. L. Kenly, former commander of the air forces in France, both acting as advisors.

The use of lighter than air craft for commercial air transportation is a certainty of the future, declared General Kenly in his addess to the delegates.

"Because of the Roma and Z R-2 disasters there is no reason why lighter than air craft cannot be developed," said General Kenly. "Lighter than air craft is coming, as sure as life. The public at present knows heavier than air machines, but is not acquainted with dirigible baloons. However, the need of lighter than air craft will be felt in the inauguration of an extensive commercial system.

"This country has practically a monopoly on helium. I believe helium can be produced on a commercial basis and at a comparatively low figure.

"Two years ago, a board of engineers representing the American Investigating Corporation went abroad to probe development of lighter than air machines. After a year of investigation, during which they visited England, France, Germany and Italy, the engineers reported the project was feasible commercially. They found the Germans far ahead of the other countries in the development of lighter than air craft.

"One of the results of this report has been tbe formation of the General Air Service. This firm has acquired certain rights on German inventions in the lighter than air machines and now is devoting its attention to the possibilities of commercial helium.

"With helium and properly constructed machines we can travel anywhere with perfect safety. But there also will be further opportunities for heavier than air craft. When the great lighter than air machines are working on established routes, the heavier than air machines could be used to good advantage in forming quick 'feeders.'"

A paper by Samuel S. Bradley, general manager of the Aeronautical Chamber of Commerce, and read by J. B. Harvey, Kansas City delegate, pointed out the growth of aeronautics in the United States in 1921.

"We estimate, from reports received by the Aeronautical Chamber of Commerce, that there was about 20 per cent more flying in the Unitd States in 1921 than during the previous year," said Mr. Bradley's paper. "This is a remarkable fact when one recalls the general business and industrial depression.

"The public has changed its mind in regard to flying. A year ago many persons believed that the present generation, which witnessed the development of the motor car, wireless and other astounding inventions, would not accept the flying machine. It was a bit too much to expect of a race that had always kept one foot on the ground, so to speak. Nevertheless, the aeroplane has been accepted.

"The general opinion prevails throughout the industry that the public has been shown and that it now is up to the public to make use of the flying machine for what it is worth. Then, let us hope to find another 20 per cent increase in flying at the end of this year.

"Half of the aeronautical activities of 1921 were carried on in the region between the Appalachian and the Rocky Mountains. Half the aeroplanes in the country are operated there. The Mississippi, Ohio and Missouri River Valleys, Colorado, Montana, the Dakotas, Iowa, Nebraska, Oklahoma and Texas afford many natural advantages, chief among them, emergency landing facilities. It is estimated that more than 300 planes were entered in flying meets in the Middle West in 1921, and that they flew a total of 500,000 miles in these meets, carrying approximately 15,000 passengers before the crowds aggregating 400,000 spectators.

"Now it is up to us, or rather, to the government, to protect commercial aviation. We must protect people and property, in flight and upon the earth, against damage, loss or nuisance from aircraft. In other words, we must secure adequate control of flight, but in a manner that will not throttle development. The problem is civilian because it pertains to commerce and industry. At the same time it is intimately connected with national defense. The Wadsworth-Hicks bill should be made a law before spring flying opens. With air laws will come capital and individual responsibility."

The science of flying in the future will be so advanced both as regards lighter than air craft and heavier than air machines that there will be intimate and general communication between all cities and towns of the country by means of aircraft, it was predicted in an address by Admiral Fullam.

"This aircraft communication will involve a transportation of mail, passengers, and, to a certain extent, freight, between communities and different sections of the country," said Admiral Fullam. "It is believed, therefore, that the organization of the Commercial Aeronautical Association of the Seventh Army Corps Area in Sioux City is a movement that will ultimately be of great benefit to every town and city that joins in the movement. It is the dawn of a new era in transportation which will benefit all business interests.

"It is clear that in a few years the enormous and expensive battleships of the present day will be so completely at the mercy of air attack, combined with submarine attack and mines and torpedoes that no more ships of this type will be built after the ten-year naval holiday. Of all these new weapons it is believed that the air forces are the most important, for with these alone a nation can absolutely protect itself from naval raids and from invasion by armies overseas.

"No fleet and no convoy can bring with them across the sea sufficient air forces to command the air after they reach our coast, provided this country supplies itself with strong air forces for the use of the army and navy. In this con-

Digitized by Google

nection commercial aviation, involving the use of both heavier than air and lighter than air machines is of the most vital importance to our country, because all such forces, with their personnel, could be rallied as a reserve in time of war.

"It is my belief that aviation has great practical uses and that safety in flying has been secured to such an extent that we may discount all fear as to the dangers involved. In Europe, men of big interests are flying all over the continent to keep their dinner engagements. Lighter than air craft development will unquestionably be recognized soon as a safe and reliable means of transportation."

The following officers were elected for the Seventh corps organization: Ralph W. Crum, Davenport, Ia., president; M. F. Stack, St. Louis, first vice-president; J. B. Harvey, Kansas City, second vice-president; W. B. Swaney, Fort Dodge, Ia., third vice-president; John W. Coleman, Sioux City, secretary, and C. H. Wolfley, St. Joseph, Mo., treasurer, The board of directors will consist of the officers and E. R. Schultz, Sioux City; J. L. McNeill, Des Moines, and A. R. Dunphy, Omaha.

The office of the secretary, John W. Coleman, is located at 315 Metropolitan Building, Sioux City.

THE BELGIAN PLAN OF SUBSIDIES FOR AIR TRANSPORT COMPANIES

Subsidies

SUBSIDIES are of two kinds:

(1) Subsidies based upon the hours of flight and the distance covered.

(2) Commercial efficiency subsidies proportional to the gross receipts.

The subsidies under (1) comprise:

(a) An amortization subsidy;

(b) A course subsidy.

The amortization subsidy is determined by the formula $\frac{P + 1.5\ p}{200}$ where P represents the value of the cellule (in francs) and p the value of the engine group (in francs,) each increased by 20 % to include the costs of upkeep and insurance.

The value of the cellule and engine group is fixed by the Technical Commission of the Administration of Civil Aeronautics at the time of the proposal of the Service.

The course subsidy is determined by the formula $\frac{K}{1000} \times V^2 \times 1.5\ T$, where V represents the speed, T the useful load and K a variable. The speed V is measured in kilometers per hour at 2,000 meters. T is the load in tons after the following have been deducted:

(a) The weight of the crew (computed at 80 kg. per person.)

(b) The weight of the navigation instruments.

(c) The weight of the fuel.

The load factor of the aeroplane must be at least 5.

The practical ceiling (height attained after one hour of flight) must be at least 4,000 meters with full load.

The aeroplane must be able to cover a course of 500 kilometers with a contrary wind of 10 meters per second, admitting that the speed of the aeroplane is its speed at 2,000 meters and that the consumption of the engine is that taken on the ground and at full power.

The value of K is fixed as follows:

Mean length of Course (in kilometers)	200	201 300	301 400	401 500	501 600	601 700
In Belgium............	3	4	5			
International..........	4	5	6	7	8	9

The number of hours of flight subsidized is calculated by following the itinerary determined at a fixed speed of 130 k. p. h. The course will be measured in a straight line from the point of departure to the point of arrival unless an obligatory itinerary is fixed by international agreements or national rules. In these cases the course will be measured by the broken line which passes through the center of the airway imposed and which avoids the forbidden zone. Journeys will not be subsidized which are not completed or which exceed the normal duration by 50% (normal duration being the quotient obtained by dividing the distance D by the commercial speed of 130 k. p. h.) However, in the case of special atmospheric conditions properly noted and proved, complete journeys made with several stops may be subsidized when they have been made in a length of time showing a gain of at least 25% over the fastest means of public transport on land or sea.

Except in the case of "force majeure" properly noted by the Chief of the Aerodrome or his delegate and of which mention must be made in the log book, a delay in departure of ¼ of an hour incurs a reduction of 5% in the time subsidy. The same reduction applies to each ¼ hour or fraction thereof which follows.

The time subsidies fixed above can be increased or diminished according to the degree of punctuality attained. A coefficient of variation is established monthly as a function of the regularity of service. The regularity is defined by the proportion of the number of journeys subsidized to the number planned (extra authorized trips being excluded.) The coefficient of variation will be equal to the above proportion expressed in hundredths, increased for the months of December to March inclusive by 35/100 and for the other months by 25/100. The monthly total of the time subsidies to be paid is then multiplied by this coefficient, thus giving the net sum to be paid.

The amount of the commercial efficiency subsidies is in direct relation to the reduction made in the fares, and varies according to whether it concerns passenger or freight.

(a) *Subsidy for passengers.*

To benefit by this subsidy the passenger fare must not exceed 1.25 fr. per km. This subsidy is given according to the following method:

For all reductions of less than 10% from the fare of 1.25 fr. per km. a subsidy of 60% on the receipts is given.

For reductions of 10% to 19% inclusive, from 20% to 29%, from 30% to 39% and for 40% or more, subsidies of 90%, 120%, 150% and 180% respectively, are given on the receipts.

(b) *Freight subsidy.*

To receive this subsidy the charges for freight transport must not exceed 0.02 francs per kilogram per kilometer. The subsidy is calculated as follows:

Every reductions of less than 20% from the cost of 0.02 francs per kilogram per kilometer gives the right to a subsidy of 35% of the receipts.

Reductions of 20% to 29% inclusive, 30% to 39%, 40% to 49% and 50% or more are compensated by subsidies of 60%, 85%, 110% and 135%, respectively, of the receipts.

Conditions Required to Obtain Subsidies

(a) The Company must be Belgian.

(b) The capital of the Company must be at least equal to the amount of the annual subsidy which it will receive, supposing that all the journeys proposed are covered and taking into account only the time subsidy.

The capital will be represented either by buildings or material (the value of aeroplanes being that fixed by the Administration of Civil Aeronautics,) or by supplies or hangars (intended only for the proposed lines,) or by subscriptions of which the total payment may be required by the State.

The origin of the capital, all necessary information in regard to the shareholders and the names of the directors must be communicated to the Administration of Civil Aeronautics at the time of formation of the Company or on any change in it.

(c) The personnel directing the Company must be of Belgian nationality.

(d) The pilots and mechanics are to be in general of Belgian nationality. The employment of foreign pilots and mechanics will be authorized only in case of lack of Belgian personnel.

(e) The aeroplanes used must possess their navigation certificates and Belgian licenses.

(f) The pilots must be provided with the Belgain licenses as pilots for aeroplanes for public transport.

(g) The services which the Company proposes to effect must be of public or national interest and offer a great improvement over existing means of transport.

(h) In general no Company will be subsidized which does not maintain a daily service over Belgian territory or to foreign points if within 250 km. of the Belgian frontier. In the case of more distant points the service must be at least three times per week.

(i) The fares must be agreed to by the State.

(j) In case the Company should use private landing fields they must be acceptable to the Administration of Civil Aeronautics.

Obligations

The State requires a minimum number of aeroplanes, pilots and mechanics in the interests of regularity and safety of the services.

Digitized by Google

The required minima are:

1. For aeroplanes. Twice the number of aeroplanes which will be used up during the operation of the service. The number is calculated by taking the life of the aeroplane as 200 flying hours and the speed as 30 k. p. h. The number of aeroplanes therefore will be the

daily course (in kms.) x number of days of operation.
200 x 130

Note: If a fraction is obtained, the number of aeroplanes required will be increased to the next whole number.

2. For pilots: half of the number of aeroplanes.

3. For mechanics: one for every 300 HP employed in the total number of aeroplanes.

The subsidized companies are required to equip their aeroplanes with all devices and arrangements to assure the public the maximum of safety and comfort and to carry out the orders of the State which may be made in this respect.

The subsidized companies are required to place their installations, material, and all their resources at the disposition of the State from the first day of mobilization of the Army, according to the plan of mobilization made in agreement with the Director of Aeronautics.

Penalties

If the regularity of service is not maintained owing to lack of personnel or material, poor organization or any other cause except "force majeure" and in the case of non-compliance with these regulations, the Director of the Administration of Civil Aeronautics may suspend the subsidy of the Company. In case of bad weather, departures may be delayed or suppressed by agreement between the representatives of the Government and the Company. The decision of the Government's representatives is final without, however, incurring the responsibility of the State.

If during three consecutive months the efficiency of the line drops below 25%, that is, if the total of paying passengers and freight carried is less than a quarter of the total available seats and load capacity the commercial efficiency subsidies will be suspended until the efficiency becomes more than 25%.

Non-compliance with the regulations contained herein entails the following penalties:

1. Warning.
2. Suspension of subsidies for one month.
3. Permanent suppression of subsidies.

Control

The control to which the companies are required to submit is of two kinds.

Technical control (bearing on the personnel and material employed.)

Administrative control.

Technical Control

This control is in the hands of a Technical Commission designated by the Administration of Civil Aeronautics and is made:

On presentation of proposal.

On starting the service.

During the course of the service.

(a) *On presentation of proposal.*

The companies must send to the Administration of Civil Aeronautics forms giving the state of the material and personnel.

The Technical Commission is to assure itself:

1. That the aeroplanes to be used by the Company possess their Certificates of Navigation and are in perfect flying condition.
2. That the special modifications do not decrease the worth of the aeroplanes.
3. That the aeroplanes can fulfill the conditions (length of flights, load carried, etc.)
4. That the pilots and mechanics possess the proper licenses.
5. That the private landing fields used by the Company are in proper condition.

(b) *On starting the service.*

The Technical Commission verifies the identity of the conditions at this time with those mentioned in the proposal.

(c) *During the course of the service.*

The services are required to submit the first of each month forms relating to the condition of the personnel and material.

On variable dates the Technical Commission notes whether the pilots, mechanics and aeroplanes continue to possess the necessary qualities.

Administrative Control

This control is made by the proper services of the Administration of Civil Aeronautics.

(a) On presentation of a proposal.
(b) On starting the service.
(c) During the course of the service.

(a) *On presentation of proposal.*

The control service is to assure itself:

1. That the Company is Belgian.
2. That the persons directing the enterprise are Belgian.
3. That the Company employs pilots and mechanics of foreign nationality only if Belgian pilots and mechanics are lacking.
4. That the Company possesses and will place in service the minimum number of pilots, mechanics and aeroplanes required by the State.
5. That the rates charged will not exceed those fixed by the State.

(b) *On starting the service.*

The control service verifies:

1. The agreement of the conditions of the starting of the service with those of the proposal.
2. Whether the aeroplanes have the proper Belgian licenses.

(c) *During the course of the service.*

The control service is to assure itself of the regularity of the service.

The Companies must send control forms to the Administration of Civil Aeronautics the 1st, 11th and 21st of each month.

In order to assure the execution of the article given above relating to penalties for delay in starting, a register will be kept in each aerodrome. The delays with their causes will be inscribed on a sheet signed by the Chief of Aerodrome and pilot or representative of the Company on the field.

To permit verification of the passengers and freight transported, the Companies must present to the Administration of Civil Aeronautics at the end of each month a resume of the passengers and freight carried during the month with the numbers of the tickets and luggage receipts as well as the prices of each.

At the time of arrival and departure the Companies must furnish to the Chief of Aerodrome all information judged necessary to control the subsidies.

The Companies must supply at the request of the Administration of Civil Aeronautics complete and detailed information as to their expenses and receipts as well as their balance sheets.

FULL SCALE DETERMINATION OF THE LIFT AND DRAG OF A SEAPLANE

By MAX M. MUNK

Technical Note National Advisory Committee for Aeronautics

Summary

The speed, barometric pressure, and number of revolutions of the engine of a seaplane were measured, including tests with stopped engine. The mean data obtained are given in the following note; the results of the gliding tests are used for the computation of the lift and drag coefficients, and by making use of them the results of the engine flights are used for the computation of the propeller efficiency.

The free flight tests described in this note were made by the author and Dr. Erich Hueckel at the testing station at Warnemuende during the summer of 1918, and are here published for the first time. It was intended to develop a simple method for the examination of the aerodynamical properties of a seaplane independent of the characteristics of its propeller. The instruments had to be simple and self-recording, and no long preparation of the aeroplane for the test could be allowed. On the contrary, the instruments had to be mounted in the aeroplane only a short time before the beginning of the test. The method was used with one aeroplane only, and the opportunity was taken to determine its lift and drag cofficients and the propeller efficiency.

The seaplane used for these tests was a German Brandenburg sea-biplane with the following characteristics:

Digitized by Google

Spans 36'-9" and 34'-5½"
Entire wing area, S, 380 sq. ft.
Entire weight, W, 3,200 lbs.
Two floats, two pairs of struts.
Propeller diameter, D, 9' 2¼"

The instruments used for the tests were a chronograph and an ordinary barograph. The first instrument was similar to a Morse telegraph receiver; a paper strip about 1¼" broad moved with a velocity of about 7" per minute under four needles, which when under the influence of four independent electromagnets, marked the paper without stopping its course. The needles were controlled respectively by an ordinary clock-work, by the flexible shaft of the revolution counter of the engine, by an anemometer of the Robinson type and by hand. The clock gave electrical contacts at intervals of 12 seconds, the shaft leading to the revolution counter always after 2 revolutions of the shaft, corresponding to 52 revolutions of the engine. The anemometer gave contact after each 180 feet of travel of the aeroplane approximately. The fourth needle was operated mannually by the observer when the altimeter had reached certain points. It was intended to operate the fourth needle automatically too at later tests, making it indicate the density of air. Readings were also made of a thermometer, but the greatest part of these could not be used, for it appeared subsequently that the thermometer was too near to the exhaust. The density therefore had to be calculated. This was done by means of the formula $\rho = \frac{1}{8}\,.9^h$ kg sec^2 m$_4$ where he denotes the altitude in kilometers as indicated by the altimeter.

Gliding Tests.—The pilot controlled the aeroplane so that the dynamic pressure as indicated by the pilot tube was nearly constant. The velocity decreases then during the dive and the negative acceleration of the aeroplane is to be taken into account in the computation of the final results. The path is slightly curved too, but the centrifugal force is neglected in this paper. Let w denote the vertical velocity and v the total velocity, and let the angle ϵ be defined by the relation $\sin \epsilon = w/V$. The slope of the path then is taken into consideration if the usual formula for the power is replaced by the following formula

$$\frac{C_D}{C_L^{3/2}} = -\frac{w}{\cos^{3/2}\epsilon}\sqrt{\frac{S}{W}\,\frac{\rho}{2}}$$

which for small angle ϵ assumes its ordinary form.

C_L is calculated from the formula $W = C_L\, q\, S$ and, on substitution in the preceding formula, C_D is deduced.

All instruments were carefully gauged before each test; the weight of the aeroplane was deduced for each test by taking account the weights of the pilots and the estimated consumption of fuel. The table at the end of the note gives the mean values obtained from each series of tests.

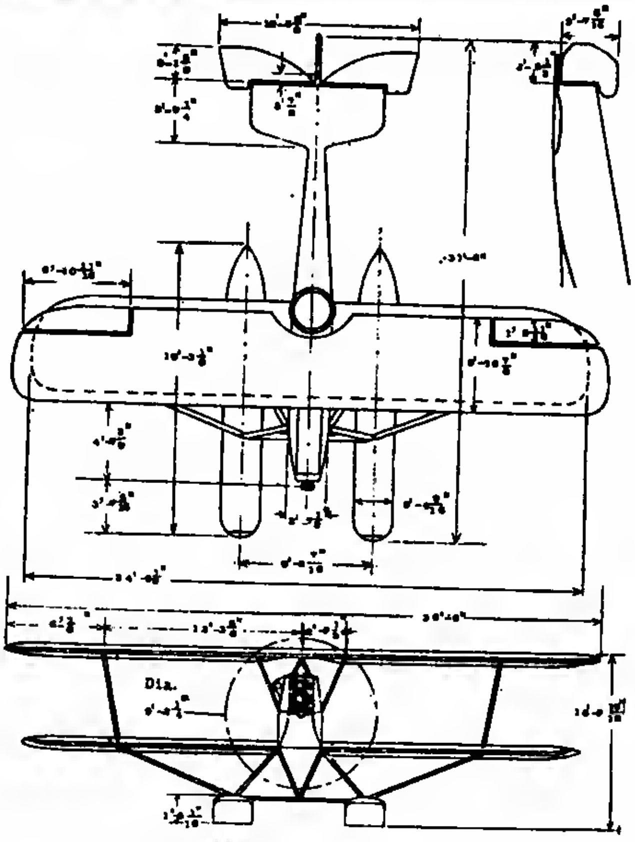
Tests With Running Engine.—The horsepower of the engine was assumed to be

$$N = \frac{n}{n_o}\,\frac{\rho - .015}{.125 - .015}\,N_O$$

where N_O is the power delivered at the normal number of revolutions n_O and at the density of the air 0.125 kg sec^2/m^4, and ρ is the density of the air in the same units.

The mean results are contained in the table. The efficiency of the propeller was deduced by making use of the drag coefficients obtained by the gliding tests; the drag of the propeller for the stationary aeroplane determined by a model test, being subtracted.

The efficiency thus obtained includes the loss involved by the mutual influence of propeller and aeroplane, consisting of an increase of the drag, which in general is not wholly neutralized



Brandenburg Seaplane.

by the increase of the propeller thrust. That is, the efficiency is

$$\frac{C_D\, S\, q\, V + u\, W}{\text{Brake horsepower}}$$

where u denotes the vertical component of the velocity. This absolute efficiency is different in general from the original efficiency of the isolated propeller.

No.	Gliding Tests						Engine Running

MANOMETER FOR RECORDING AIR SPEED

By C. WIESELBERGER*

PRESSURE gages are largely used for measuring the speed of an areoplane with reference to the air (actual speed), in which connection the pressure difference is measured with the aid of a manometer. This pressure difference in some forms of the instrument (for instance, Prandtl's pressure gage) gives the pressure directly, but in other forms is proportional to it. If it is desired to record the pressure difference given by the gage, the manometer must answer the following conditions:

1. It must respond quickly so that all speed variations will be correctly recorded.

2. It must not be affected by rectilinear or curvilinear accelerations. Hence, movable parts must be counterbalanced.

On account of the smallness of the pressure to be measured (the dynamic pressure being q = 156 kg/m^2 = 1/64 atmosphere, with air density $\rho = \frac{1}{8}$), the friction of the movable parts of the instrument must be eliminated as much as possible. Since the dynamic pressure is obtained as the difference between the total pressure and the static pressure, there are two pressures to be measured. In the present instance, this is done by conducting the total pressure under a box made of very flexible membranes (Fig. 1) while the static pressure is made to work on the cover of the box by inclosing the whole in-

* Taken from "Zeitschrift für Flugtechnik und Motorluftschiffahrt."

Digitized by Google

strument in an airtight case, in which the static pressure rules. In this way, only the difference of the pressures affects the cover of the box. The pressure exerted on the cover is received by a spring. The box is so thin that no appreciable elastic reactions are produced, provided the forces act for only short distances. Hence the distance transversed from the cover of the box is proportional to the dynamic pressure. This distance is enlarged by the lever shown in the diagram and recorded on a drum. If only a short distance is left to the box and this distance is correspondingly magnified by a light lever, a short oscillation period is obtained and a correspondingly rapid response of the instrument.

In order that no acceleration may affect the instrument readings, the following counter-balancing must be done. It is first essential to render rectilinear accelerations non-effective in both the horizontal and vertical directions. This is accomplished by means of the counterweights P_1 and P_2, which, in the acceleration of the instrument on account of its influence of inertia on the lever h_2, exert a moment offsetting the moment produced by the lever h_1, so that the pointer is not deflected. As regards the curvilinear accelerations, it is most important to offset those whose rotation axis is at right angles to the recording surface. These accelerations are rendered harmless by making the moments of inertia Θ_1 and Θ_2, of the levers h_1 and h_2, bear the same ratio as the lever arms a and b, hence $\Theta_1 : \Theta_2 = a : b$. The mass of the box cover, with half the mass of the box and the spring, is thereby to be included in Θ_1. A curvilinear acceleration then generates in the connecting rod s a momentum coming from the lever h_1, which is of like magnitude but opposite in direction to the corresponding force from the lever h_2, so they mutually offset each other. In order that the inertia moments may satisfy the prescribed ratio, there are placed on the lever h_2 two like weights G equally distant from the pivot d_2. By varying the distance of these weights from d_2, the moment of inertia of this lever can be temporarily adjusted. Curvilinear accelerations about the other horizontal axis and about the vertical axis likewise generally produce moments on the lever axes. In order to eliminate the effect of these moments, the lateral positions of the counterweights P_1 and P_2, on the axis of h_2, must be so chosen that the moments arising on the lever h_1 will offset those on the lever h_2.

When employing the manometer on rapid climbing aircraft, still another precautionary measure must be taken, in order to avoid the variometer effect of the instrument, which is caused by the volume of the case being considerably greater than the volume of the box. If the instrument is placed, for example, where the external pressure is higher, a certain interval of time will elapse, on account of the compressibility of the air, before the higher pressure has reached a state of equilibrium in the case, while this takes place more quickly in the box, on account of its smaller volume. The result is a deflection of the manometer. In order to prevent this, the air is likewise admitted slowly into the box, which may be accomplished by placing a suitable valve in the air inlet pipe. The amount of the throttling depends on the resistance of the air inlet pipes to the instrument. Of course it also has the effect of damping the instrument, but not enough to affect its responsiveness very much.

The instrument was made in the workshop of the Göttingen aerodynamic laboratory. The box is made up of ring-shaped corrugated membranes of sheet brass 1/20 mm. thick, soldered to brass rings. The pivots of both levers consist of knife edges, in order to keep the friction as small as possible. They are held

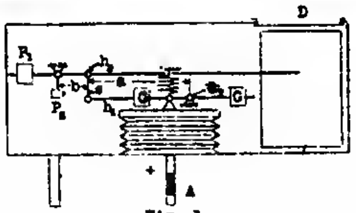

Fig. 1.

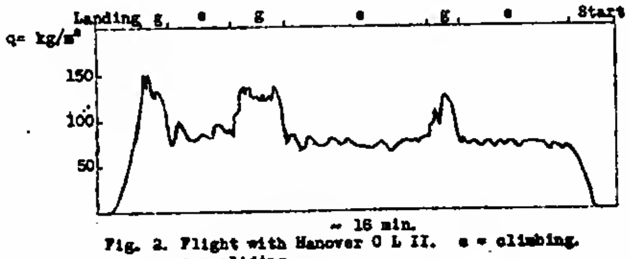

Fig. 2. Flight with Hanover C L II. s = climbing. g = gliding.

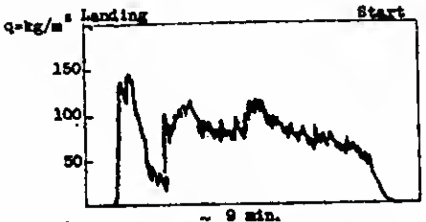

Fig. 3. Flight with Halberstadt C L IV in very squally weather.

lightly against their supports by spiral springs. All the other joints consist of leaf springs. The measuring spring is removable, so that the measuring scale may be changed when necessary. The stylus is made very light of thin sheet aluminum. The record is made on smoked paper. The drum can be introduced or removed after removing the cover D. The clockwork which drives the drum can be started or stopped by turning a small eccentric button on the bottom. The valve for preventing the variometer effect is located at A.

The instrument gave a good account of itself in the trial flights made at the end of 1919 under the supervision of Professor Proell of the Hanover Car Works. Figures 2 and 3 reproduce two of the records, on which all the details of the pressure variations can be readily recognized. That the counterweights actually produced the desired effect is demonstrated by the fact that the record shows no trace of the engine vibrations, while the record of another manometer, not counterbalanced, was spread out by these vibrations in the form of a band. In squally weather, no utilizable record could be obtained with the latter instrument. The drum, driven slowly by the clockwork, was occasionally rotated slightly in the opposite direction by the very strong vibrations. This effect found expression in a peculiar wave form in the vertical lines (Figure 3).

Translated by National Advisory Committee for Aeronautics.

French Aeronautics

It is reported that the prize of one million francs offered for the best aero engine will probably be augmented by another million, offered by the French Air Minister, for engines of 350 to 450 h.p., and weighing not more than 2 lbs./h.p. It is understood that competing engines will have to pass a reliability run of 240 hours, in stretches of eight hours each, and that the total time taken in completing the 240 hours must not exceed 100 days. The competition will start on March 1, 1924, and entries must be received before December 1, 1923.

Announcement has been made that the Aviation Committee of the Colonial Exchequer have definitely decided to organize a contest for seaplanes from April 17 to 19, under three classes: under 150 h.p.; 150 to 400 h.p.; and over 400 h.p. Eliminatory trials are to take place on April 17, when entered aircraft must ascend to 1,000 metres, and have on board, in addition to the normal useful load, sufficient fuel for 1½ hours flight. The course, Marseille-Monaco, is 413 kilometers. Prizes to the extent of over 40,000 francs are offered.

Belgian Competition

The Aero Club of Belgium has organized an International Competition for touring airplanes to be held at Brussels on June 23-25, 1922. The competition is open to touring machines, single-seaters or multi-seaters, whose engine capacity does not exceed 7 litres. The awards will be made for a total of 100 points, allotter as follows: 30 points for minimum space occupied in hangar; 30 points for general economy of the engine; 25 points for slow landing, and 15 points for quick get-off. The prizes are as follows: The King of Belgium's Challenge Cup, to be retained by the winner for one year; and the following cash prizes: 1st prize, 15,000 francs; 2nd prize, 7,000 francs; and third prize, 3,000 francs.

Argentine Aerial Club Opens

Consul General W. Henry Robertson, Buenos Aires, states that on January 6, 1922, the new flying ground and school acquired by the Argentine Aerial Club at San Isidor, alongside the grounds of the River Platte Aviation Co., were opened for use, more then 20 machines taking part in the ceremony.

Opportunity in Colombia

According to Mr. Edmund B. Montgomery, American Vice Consul at Barranquilla, Colombia offers an opportunity for the establishment of an air transport service. The facilities and carrying capacity of such a service, however, must be greater than that rendered by the present company (Colombian-German Aerial Transport Co.), which maintains a hydroplane service, and which, for the months of October, 1921, to January, 1922, inclusive, reported 307 flights, aggregating 57,640 kilometers, 303 passengers carried, and 29,280 kilograms of freight transported. This company has a contract to carry mail for a period of five years, the Government subsidizing it to the extent of $100 per trip.

As the river steamship transportation is uncertain in the dry season, which is now coming on, an air service with machines carrying 10 to 14 passengers would undoubtedly get all the passengers and freight that could be carried, although one drawback to large air boats on the river is the danger of contact with driftwood in starting and landing. The ratification of the American-Colombian treaty should be a help in any negotiations which may have for an end the establishment of such a hydroplane service on the Magdalena River by American interests in co-operation with Colombians.

COMMERCIAL AVIATION DEVELOPMENTS IN EUROPE

By W. KNIGHT, M. E.

(Continued from page 109)

RUMANIA

Commercial aviation in Rumania has actually started its activities in 1921. In fact, it was only last October that the first aeroplane of the "Franco-Romane Aerial Transport Company" made its first flight from Paris to Bukarest.

The line Bukarest-Paris-Constantinople is going to be operated regularly this year. The trip from Paris to Bukarest will be made by starting from Paris at 6 P. M. and arriving at Bukarest two days after, early in the morning. For the year 1922, the "Franco-Romane Aerial Transport Company" will have an aeroplane provided with sleeping quarters for 20 passengers which shall be used on the line between Paris and Bukarest. This company is already operating the lines between Paris and Praga and between Paris and Warsaw.

Tbe capital of the company is 10,000,000 of francs. This company, we might say, is an enterprise mostly financed and supported by French capital. In fact, the French Government gives 9 millions of francs per year as a subsidy to this company and the President of this company itself, is General Duval, former Chief of the Air Service in France.

The Polish Government also gives to this company 1,000,000 francs per year subsidy, payable in oil and fuel and, besides this, grants to the "Franco-Romane Aerial Transportation Company" the exclusive operation over the Polish territory for ten years.

The Czecho-Slovak Government also pays a subsidy of 5 million crowns per year, and grants to the company the exclusive right of operation for ten years. The Turkish Government grants to this company the monopoly for the transportation of the mail between Bukarest and Constantinople for five years, subject to renewal. The Rumanian Government, besides paying a subsidy to the company, grants it the exclusive right of operation on the line Paris-Strasbourg-Praga-Vienna-Bukarest-Constantinople.

The following project for the development of civil aviation in Rumania has been submitted by Mr. Mirea, Director of the Air Service under the ministry of transports in Rumania. The project starts with considering the following nine international lines passing through Bukarest.

1. London-Paris-Vienna-Budapest-Bukarest.
2. Trieste-Belgrad-Bukarest.
3. Athens-Salonica-Sofia-Bukarest.
4. Constantinople-Adrianople-Bukarest.
5. Constantinople-Costanza-Bukarest.
6. Hamburg-Berlin-Praga-Vienna-Budapest-Bukarest.
7. Dantzig-Warsaw-Leopoli-Bukarest.
8. Bukarest-Chisinau-Kiev.
9. Bukarest-Odessa.

In conjunction with these nine international lines, the following lines shall be operated:

1. Bukarest, Craiova, Trunu, Severin, (effecting the liaison with Belgrad); Temesvar (liaison with Seghedin, Budapest); Avad, Orodia (liasion with Delretin, Budapest).
2. Bukarest, Giurgin (effecting liaison with Sofia, Athens, Adrianople, Constantinople).
3. Bukarest, Tecuci, Iassy (liaison with Warsaw).
4. Bukarest, Costanza (liaison with Odessa and Constantinople).
5. Bukarest, Braila, Galatz, Chisinau (liaison with Ukrainia).

Besides these lines, connecting together the various international lines, the following lines for the local traffic shall be operated:

Bukarest-Brasov, Bukarest-Pitesti-Sibiu-Cluj-Orodia, Galat-Tecuci-Brasov-Sibiu.

Airdromes for these lines shall be provided at Bukarest, Craiova, Temesvan, Orodia, Costanza, Iassy, Vernovitz, Balatz, Chisinau, Turnu. Severin, Arad, Giurgin, Tecuci, Braila, Brasov, Pitesti, Sibiu, Cluj.

This project comprises also the establishment of an aircraft manufacturing plant capable of an output of 300 aircrafts per year. The capitalization of the company undertaking the development of this plan has been anticipated to be 260 millions of lires and the total cost of operation per year has been figured to be 144 millions of lires. The realization of this project will be effected mostly with foreign capital. French and British capital seem to be very much interested in its development and every facility will be granted by the Rumanian Government for the realization of this undertaking.

OTHER COUNTRIES

Besides France, England, Belgium, Italy, Germany and Rumania that we have considered so far, minor attempts for establishing civil aviation are more or less apparent in the rest of Europe. In some countries like Switzerland, we find that civil aviation activities are intimately connected with the tourists traffic and when we consider the beauty of the panorama of the Alps which can be obtained by flying over the mountains, we might expect quite a lively development of civil aviation there, however limited to excursions over the Alps and the lakes of Switzerland.

At the present time, the "Ad-Astra" of Zurich, is doing most of the commercial flying carrying passengers for excursions and also for taking photographs of the Alps from the air, which are sold to tourists at a good price.

A number of aerodromes and hangars have been constructed at Dudendorf, Geneve, Cointrin, Lausanne Blucherette, by the department of civil and military aeronautics. At Dudendorf especially, they have a fine aerodrome with twenty hangars and all modern facilities for testing motors and propellers.

Hangars and aero-ports for hydroplanes are to be found at present at Geneve, Lausanne-Ouchy, Locamo, Lugano, Lucerne, Korschack, Romanschorn and Zurich.

Landing fields for aeroplanes are now open at Avenches, Bellinzona, Zurich-Spreintenbach, Aaran, Berne, Biere, Colombier, Frauenfeld, Thun and about two dozen of private landing fields are scattered all over the country.

Due to the geographical position of Switzerland and the Alps, which in some places reach in height to nearly 14,000 feet, international lines operated with commercial aeroplanes which are not designed for flying at very great altitudes shall find a barrier in Switzerland and shall have to avoid the route over Switzerland, in spite of the fact that it would make a short flight to fly directly over the Alps rather than circling around them over the routes, Paris-Venice, London-Milan, Munich-Bordeaux, Vienna-Lyons, etc.

There is now a project in Switzerland of forming a local company equipped with aeroplanes designed for carrying passengers with a sufficient degree of comfort over great altitudes, manned by pilots, well familiar with the exceptional atmospheric conditions prevailing over the Alps. This company would operate in connection with the international lines crossing over Switzerland and would take care of the transportation of the passengers from one side to the other of the Alps. In other words, this company would operate aeroplanes like shuttles over the Swiss border.

In Sweden, some attempts have been made by the Svanska Luftrafik, A.B., last year for establishing an air mail service. The operation of this company, so far, is in an experimental stage. In the three months of July, August and September of last year, this company has operated the line, Stockholm-Reval, and 800 kilograms of mail matter have been transported. The distance between Stockholm and Reval is only 280 miles, which were covered on an average of between 2½ and 3 hours. Only 21 passengers have been transported and 92% of the scheduled trips were completed in the above named period of time.

In Spain, besides the French line operating between Perpignan and Casablanca there is the Madrid-Alicante line operated by a private concern and the Melilla-Algesiras operated by the Government. A project for a dirigible line between Spain and South America is now being considered.

In Norway, in the Netherlands and in Czecho-Slovakia some noticeable signs of real activities are to be found.

In August, 1919, "The International Aircraft Association, Ltd." (I.A.T.A.) was formed for the purpose of insuring a uniform exploitation of international lines, so as to avoid competition by agreeing on standard rates and technical requirements of aircraft used by the Aerial Navigation Companies in the membership of the I.A.T.A. At the present time, the following companies have joined the I.A.T.A., Danske Luftfartselskab, Denmark; Danziger Luftreederei, Free State of Dantzig; Deutsche Luftreederei, Germany; Finska Luftrafik; Finland; Koninklijke Luchtvaart Maatschappij, Holland; Svenska Luftrafik, Sweden.

Conclusions

From the summary review that we have made of the status of civil aviation in Europe at the end of 1921, we might draw

Digitized by Google

a few conclusions which might be useful to us in establishing and operating aerial lines in this country.

The outstanding feature of Aerial Transport Companies in Europe, has been, first, the great interest shown by European Governments in providing these companies with sufficient subsidies to allow them to survive the first few years when they will have to operate at a loss, and also in providing a good organization of the aerological and wireless services, landing fields and signals for night flying, which facilitate the operation of the aerial lines and insures to a great extent, the safe operation of aerial routes.

Second, almost every aerial transportation company operating at present in Europe, is using aircraft not well adapted to the commercial exploitation which is required of them. Third, the cost of operation of these lines is greatly increased due to insufficient volume of commercial load and passengers carried over the lines flown. The cost of a ton per mile is too high as yet to successfully compete with other existing means of transportation. This being especially true over short lines where the saving of time effected is hardly in proportion with the increased cost of transportation.

The high cost of operation is due mainly to the overhead expenses which are entirely and unavoidably high as compared to the volume of business handled and is also due to the type of aircraft used.

The present limit of from 100 to 200 flying hours before overhauling aerial engines is ridiculous. Motor car engines have run 80,000 miles or perhaps 3,000 hours before overhauling, (and air engines run in far better conditions than any of the motor car engines).

The life of the most of the present commercial aircraft as used in Europe, is entirely too short and the depreciation of these aircraft over a rather short period of time must necessarily increase the cost of operation.

Insurance rates are at present too heavy a burden for the exploitation of aerial lines but this again is due mainly to the types of aircraft used and is due to the unperfected ground organization. A real sound ground organization will avoid accidents and will save labor expenses to the extent of something like 30% on the cost of that item in a carelessly administered business.

The present tendency in Europe is to effect both a vertical and horizontal combination of aircraft operating companies and aircraft manufacturers. This is of course, a sound policy which will prevent competition in rates and will act as a spur to each company for supplying better services and thus securing more business.

In Europe, laws and regulations affecting aerial navigation are being developed for both international and national operation of aerial lines. A good deal is yet to be done along these lines and the future of civil aviation developments along national and international lines depends on sound laws and regulations providing a fair guarantee of safety for the passengers, without imposing unnecessary restrictions to the operating companies which would hinder the commercial exploitation of aerial lines.

(*Continued from page* 135)

ful and the air perfectly smooth. By this time the sky to the froot had become entirely clear, the rest of the journey being made under the characteristic weather conditions of Texas, and without event. Ellington Field was reached at 10:15, and the Chief of Air Service immediately started an inspection which carried him up to some time after four o'clock. During this time he met all the officers of the field and gave them a short talk with reference to plans for Air Service troops in the 8th Corps Area. The talk was followed by a luncheon, after which an aerial review took place. Machines took off in formation in spite of the cross winds and bumpy air. Lieut. Johnson demonstrated great skill in flying in his demonstration of the Thomas-Morse pursuit plane. Aerial gunnery and bombing added much interest to the flying.

Prior to his departure for Washington that night, the General attended a dinner in his honor given by the Houston Chamber of Commerce at the Rice Hotel.

The Hawaiian Divisional Air Service

The 4th Squadron (Observation), Capt. H. H. Young, commanding, which has been stationed at Luke Field since January 24, 1920, has been relieved from duty with the 5th Group and ordered to proceed to Schofield Barracks to become the nucleus of the Hawaiian Divisional Air Service. Henceforth the function of the squadron will be solely observation in conjunction with problems affecting the Hawaiian Division. Accompanying the 4th Squadron to duty with the Hawaiian Division are the 11th Photo Section and Branch Intelligence Office No. 11.

Major George E. Stratemeyer, Air Service, has been assigned as Divisional Air Officer, Hawaiian Division. The flying field selected has been used as a cavalry drill ground, is well located near the railroad and road, has sufficient space for the erection of buildings, hangars, etc., and is large enough for any type of airplane. Canvas hangars are being erected, and the field is being cleared of weeds and underbrush, which has grown up in spots. The enlisted personnel are being quartered in the 35th Infantry Barracks, and the officers are assigned quarters in the 21st, 27th and 35th Infantry areas. A study of the field is being made, and estimates of funds for necessary construction work are being prepared.

XBIA Planes on Cross Conntry Trips

During the week ending March 18th, the 13th Squadron at Kelly Field made seven cross country trips (13 flights), using five XBIA's and two DH's. These mark the first cross country trips ever attempted with the XB's, the ban on cross country on this type of plane, being only recently lifted. One plane was forced down, due to a broken oil lead, but same was repaired and the planes returned to Kelly Field without further mishap. The 13th Squadron pronounces them an ideal type of ship for cross country flying, if the vibration of the motor can be overcome. The gas consumption is very low.

Flying Time at Carlstrom Field

The records from the flying office at Carlstrom Field, Arcadia, Fla., show that the flying time for February totalled 1,563 flying hours. Some 93 student officers and cadets are at present undergoing flying instruction. These students are equally divided between two stages, and a force of fifteen dual instructors are instructing from the two stages. The present class of students will probably be the last one to learn to fly in Florida, due to the expected moving of the Primary Flying School.

Advanced Training of Flying Cadets

The advanced training of flying cadets at Mather Field is going along with particular success in smooth formation flying. Flights of eleven and twenty-three ships each have been practiced for the past ten days, with an officer as flight commander, the cadets piloting the other ships. These formations were part of the attraction at the Aerial Circus held at Mather Field on March 19th for the benefit of the Army Relief Society and the improvement of that field.

Status of 326th Observation Squadron

Excellent progress has been made in the organization of the 326th Observation Squadron, of the 101st Division, which is now 75 per cent. complete in its organization. The headquarters of the squadron is at Durand, Wisconsin; the headquarters of the 1st Flight Section is at Madison and the headquarters of the 2nd Flight Section at Milwaukee. The Squadron Commander, Captain Horace P. Orlady, will soon have completed his permanent assignment of personnel, and hope is entertained that there will be some training this year for such officers as are available. The officers of the squadron are kept informed of its progress.

Joint Training of Coast Artillery and Air Service

The War Department is taking action to insure coordination of the Coast Artillery and the Air Service in coast defense, under the basic principles of warfare and training recently laid down. The chiefs of the two combatant arms concerned have been instructed to consider together the question of joint training, with a view to carrying out experiments in joint training and tests of materal during the coming summer.

The war with Germany furnished such an exhaustive test of the powers of mobile troops that the doctrines of training for such troops were firmly established. Coast defense, however, was not so extensively tested, and many questions of the best methods and material to be used were not solved in battle. Since the war various experiments, such as the bombing of warships, have indicated the increasing power of aircraft in coast defense. It is with a view to developing the potentialities of this new arm, as well as to insure properly coordinated training, that the War Department is taking action.

Both branches undoubtedly have an important role in coast defense, and tests will be for the purpose of obtaining coordination in their training. It is expected these tests will include:

(a) Anti-aircraft target practice against air targets to determine the vertical range at which bombing planes could operate without being subjected to effective fire.

(b) Bombing practice against coast defense installations to determine the effect of aircraft bombs on such a target.

(c) Combined target practice at extreme coast artillery ranges to determine the relative efficiency of bombing planes and large caliber coast artillery guns in operation against an enemy fleet.

NAVAL and MILITARY AERONAUTICS

General Patrick on Inspection Tour

It is doubtful if any chief of a War Department Bureau or other official even on a "hurried" trip, equalled the record time in which Major General Mason M. Patrick, Chief of Air Service, accomplished an inspection tour of Air Service stations in the Southwest. When it is considered that inside of five days the Chief of Air Service inspected Kelly Field, Brooks Field, Love Field, the Helium plant at Fort Worth, Post Field and Ellington Field, one may well wonder how it was done, especially in view of the fact that at three of the stations above mentioned he spent practically the entire day going through the buildings, examining the property and inspecting the personnel.

The answer is that, outside of the journey from Washington to San Antonio, and the return journey to Washington from Ellington Field, the General utilized the quickest and most comfortable method of transportation—a DH4B airplane. Major H. A. Dargue, on duty in the Office of the Chief of Air Service, Washington, piloted the General's plane, and Lieutenants Duke and Dunton from Kelly Field in another plane acted as an escort, the two machines being company for each other in the air. When stops were made, Lieuts. Duke and Dunton rendered service in attending to the details of securing gas and oil and making careful inspections of both machines.

The weather man was in a very surly mood during several days for this record inspection trip. His ill humor, however, availed him but little, for despite lightning, rain storms, low dark clouds and Oklahoma cyclones, the trip was completed with only a slight delay. The flying was greatly enjoyed by the General, and it is the longest trip by air he has thus far made—somewhere around 900 miles. The experience gained by him on account of the varied weather conditions, especially the flight from Post Field to Love Field, will undoubtedly be of great assistance to him in dealing with matters in which flying is involved.

Proceeding from Washington on March 6th, General Patrick arrived at San Antonio, Texas, early in the morning of the 9th. He made a thorough inspection of all Air Service establishments—Kelly Field Nos. 1 and 2, the Air Service Depot, and Brooks Field. Late in the afternoon of the 9th, after the inspection of Kelly Field No. 2, a delightful reception was tendered him, in which an opportunity was given all the officers and their families to be present. Dancing, with music by the Kelly Field orchestra, was very much enjoyed, and refreshments were served. In the evening the St. Anthony Hotel was the scene of a banquet tendered the General by the field officers of the Air Service at San Antonio. There were also present at this dinner General Hines, the Corps Area Commander; General Lewis, Commanding Officer of the Second Division, and a classmate of General Patrick; General Williams, the Chief of Ordnance, who had just arrived on an inspection trip; and several staff officers of the Corps Area Commander. General Patrick took the occasion to inform the field officers during the course of the dinner of his plans to concentrate the Air Service as much as possible in the vicinity of Kelly Field. The Corps Area Commander made a few very complimentary remarks about the Air Service troops under his jurisdiction.

On the morning of the 10th, an aerial review was held, in which there was considerable formation flying and acrobatics. The GAX machine attracted a great amount of attention, due not only to the tremendous amount of noise it made, but to the expert flying performed by its pilot. On one occasion this "mighty air tank" came within inches of the ground at a tremendous speed and maintained this altitude while passing in review. The impression gained by the Chief of Air Service through the flying of the GAX was that its offensive power rested more in the roar of its motors than the roar of its canon.

The review at Kelly Field No. 2 was followed by an inspection of the Depot at Kelly Field No. 1. Following a luncheon at the Depot, the Chief of Air Service proceeded by airplane to Brooks Field and made a thorough inspection of that place, including the large airship hangar now nearing completion. Upon finishing his inspection at Brooks Field, he inspected the whole layout of Brooks Field, Kelly Field and the Depot from the air, and then proceeded to Camp Stanley to look over the bombing and gunnery ranges used by the groups stationed at Kelly Field. Observing the bombing and gunnery ranges from the air gave the Chief of Air Service a much better idea of them, it is thought, than he would have gained on the ground, as he saw the character of the surrounding country and the distance these places are from Kelly Field. He expressed the opinion that these ranges should be nearer to Kelly Field.

Early the next morning the Chief of Air Service was "on his toes" for the flight to Dallas, Texas. The day was a beautiful one, and it did not take long to roll off the many miles between the two places. The trip was made by way of Austin and Waco, and the 275 miles was covered in 2¼ hours—slightly over 2 miles a minute. During this trip the General was greatly interested in the character of the country and the air conditions, although he found he had plenty of time to read the San Antonio morning papers. At Love Field an inspection was made of the buildings and the large amount of surplus property. In the afternoon a trip was made to Fort Worth, where a thorough and very interesting inspection of the Helium plant was accomplished.

The trip from Love Field to Post Field —185 miles—was covered in a comparatively short time. The Chief of Air Service was shown Barron and Taliaferro Fields at Fort Worth (now abandoned). He saw the Helium plant from the air, and then looked over Call Field near Wichita Falls, also the great oil fields north-west of Wichita Falls, including the Burk Burnett Field. After passing into Oklahoma there was little of interest until Post Field was reached. As this was Sunday, and the visit of the Chief of Air Service was entirely impromptu, there were no formal preparations made for his inspection. He went through most of the principal buildings at the field, however, and had a very pleasant visit with the officers. In the evening a very enjoyable dinner party was held in the Commanding Officer's quarters. Weather conditions appeared to indicate that the next day would be as fine as the preceding ones for a continuation of the travel by air.

In order to obtain a good start on Monday morning for the flight from Post Field to Ellington Field, everybody arose early, only to find low clouds, high winds and rain storms. Two machines went out a little before eight o'clock to determine the feasibility of making a start, but a ceiling of only 500 feet could be attained, and so it was decided not to attempt to get away until more favorable conditions existed. By 2:30 in the afternoon the rain storms had become less frequent and the clouds had lifted, due to the strong wind, so that a ceiling of 3,000 feet was obtained. Accordingly, the start for Dallas was made, but upon progressing southward it was found necessary to keep on a line toward Forth Worth, as a very heavy bank of dark clouds lay to the eastward, pouring rain on the country and causing many places to be visited with thunder-storms and, as was learned later, with tornadoes. There seemed to be a path, however, practically cleared all the way to Fort Worth, and so the flight that far was uneventful, except for going through two small rain storms and watching the maneuvers of the heavy clouds on the left. At Fort Worth it became necessary to turn eastward and plow into this wall of dark clouds. The pilots of the two planes zigzagged around somewhat to find the most desirable place to go through, but when about midway between Dallas and Fort Worth a downpour of rain was encountered, accompanied by thunder and lightning. It was not long, however, before the airmen passed through this and were out of the rain, although forced fairly low by the heavy clouds. A landing was made at Love Field and, before the machines could be taxied into the hangar, the downpour of rain just passed through struck the field. It was too late at this time and the weather conditions too adverse to attempt to proceed to Ellington Field, and so a stop overnight was made in Dallas and plans formulated for an early start the next morning.

The weather on Tuesday morning appeared to be little better than the night before, but careful study indicated that the clouds were clearing towards the south and that better weather conditions would obtain the further south the pilots progressed, and so a start was made from Love Field at exactly eight o'clock. It was raining at the time, and the airmen did not get clear of the rain until some distance south of Dallas. A good ceiling was obtained, however, and for approximately the first hundred miles, flying at an altitude of 3,000 feet, the trip went very smoothly. Then the sun began to break up the clouds and the air became very rough. The planes ascended to a little over 5,000 feet, at which altitude the weather was delight-

FOREIGN NEWS

French Air Mail Stamps

In the French Morocco colony a beautifully engraved set of three aeroplane stamps has recently been issued. The design represents an aeroplane over the town of Casablanca. The values are 75 centimes, 1 and 2 francs.

Gothenburg Aero Exhibition

The Aeronautical Chamber of Commerce has received the program for the International Aero Exhibition in Gothenburg. Details are as follows:—

"The City of Gothenburg, the foremost Swedish port with regard to navigation and export, will celebrate the 300th anniversary of its foundation, by a Jubilee Exhibition, to be held from the 15th of May to the 10th of September, 1923, embraceing *inter alia* a General Swedish Export Exhibition and also an Exhibition by the Swedes abroad. In connection herewith there will be held the first Swedish International Aero Exhibition, 20th of July to 12th of August, 1923, in cooperation with the Royal Swedish Aero Club.

"The exhibition grounds are located in Gothenburg, on the field Exercisheden, the area of which amounts to 12,000 square meters, and besides a number of small buildings there will be erected a large exhibition hall, measuring 9,650 square meters.

"Aerocraft destined to the exhibition may land and start on the aerodrome of Gothenburg at Torsland where competitions will even be arranged.

Extent of Exhibits

Group A. Flying Machines.
1. Aeroplanes.
2. Seaplanes and flying-boats.
3. Sundry aeroplane equipment.

Group B. Balloons and Aeroships.
1. Aeroships.
2. Free balloons.
3. Moored balloons.
4. Sundry balloon and aero equipment.

Group C. Hydroplanes (gliders).
1. Hydroplanes.
2. Sundry hydroplane equipment.

Group D. Motors and Propellers.
1. Motors for aerocraft.
2. Propellers.
3. Sundry accessories.

Group E. Manufacture, etc.
1. Equipment for experiments.
2. Machinery for aerocraft factories.
3. Devices for tests and control.

Group F. General Equipment for Aerocraft.
1. Instruments for navigation and maneuvers.
2. Lighting and signalling.
3. Telegraph and telephone.
4. Photography (see group 1, 4.)
5. Parachutes.
6. Outfitting.
7. Sundries.

Group G. Material and Partly Finished Products.
1. Wood.
2. Metal.
3. Covering.
4. Pigments, dopes and varnishes.
5. Fuels and lubricating materials.
6. Sundry materials.

Group H. Aerodromes.
1. Hangars and equipment for hangars.
2. Mooring arrangements, slip-ways, pontoon docks, etc.
3. Lighting and signalling.
4. Hydrogene works.
5. Equipment for meteorological service.
6. Sundries.

Group I. Science, Literature, Instructions, Inventions, etc.
1. Aerodynamics.
2. Aerostatics.
3. Aerology.
4. Photography.
5. Laboratory equipment.
6. Training of pilots.
7. Commercial avaiation.
8. Military aviation.
9. Aer mails.
10. Literature.

"With a view to judging whether the available exhibition grounds will prove to be sufficient, or if an enlargement of the buildings must be accomplished, the Board of Administration may ask for information already previous to the 1st of April, 1922, as to the approximate space to be reserved.

"Definite application to be given on form specially established, and to be in the hands of the Board on January 1st, 1923, at the latest.

"Such application for exhibition space is to be sent in and received conformably to the directions given by the Board for the purpose. The application to contain a complete list of those objects, the exhibition of which is desired, and the permission of such exhibition is granted on the condition only that no alteration be made unless approved of by the Board. The Board reserve to themselves the right to consider the applications, and, if there be any reason, to exclude exhibits.

"Any allotment of space to an applicant may be revoked, unless the applicant within a fortnight prior to the opening of the exhibition produces on demand a proof of his being able to exhibit the articles named in his application.

"The Board reserve to themselves the right to retrench exhibition space already allotted, provided that the respective exhibitor be notified thereabout before the 1st of March, 1923.

"Offices of Board and Secretary:—Johanneburg, Gothenburg 5. Telephone Nos. 16390 and 16394. *Post Address:*—Hug, Gothenburg, Sweden.—Telegrams:—Ilug, Gothenburg."

Food by Aeroplane

It is reported from Holland that exceptionally severe weather would have imposed great hardships upon the inhabitants of the many islands which lie to the north of the Dutch mainland, were it not for the timely assistance rendered by the big Fokker aeroplanes of the Royal Dutch Air Service Company. All boat traffic having ceased owing to the ice, the aeroplanes were used to deliver large quantities of food and other supplies to the islands.

The recent railroad strike in Germany has also provided an excellent opportunity for the Dutch Company during the otherwise somewhat unprofitable winter season. The Fokker planes left Rotterdam for Hamburg and Bremen, there to connect with the D. L. R. line to Berlin, three times daily, loaded to capacity with mail, express and passengers.

Forced Landing of Plane on Mt. Vesuvius

A dispatch from Naples, dated March 16th, states that an aeroplane proceeding from Rome, of the firm Sarri of Rome, arrived at Naples a few days ago, carrying on board an American cinema "Reporter." The aeroplane was piloted by the well-known pilot, Angelo Menegelli, of Viterbo.

On the morning of the 16th, the reporter wanted to continue the flight in order to take a moving picture of Mt. Vesuvius at a very low altitude, and Mr. Menegelli conducted the aeroplane on the great crater. A military aeroplane was following Menegelli's plane, and while they were flying around the crater of the volcano and the operator was engaged in taking pictures of the abyss, the motor suddenly stopped. The pilot, however, skilfully glided his plane and prevented it from falling into the crater, landing on a small space near by. The passengers got out safely from the irregular landing place, but the aeroplane was rendered unserviceable, its wings and fuselage being damaged.

Italian Aeronautical Events for 1922

At a recent meeting of the National Italian Aeronautical Federation final determination was made of aeronautical events to take place this year, as follows:

Trophy of the County, City and Chamber of Commerce in Genoa—Genoa	May
Berardy Trophy for Balloons (International)—Milan	June
Piedmont Trophy—Turin	June
Baracca Trophy—Turin	June
Loreto Trophy—Loreto	August
Tyrrenean Trophy (International)—Naples	August
Schneider Trophy (International)—Naples	August
Italia Trophy (International)—Milan	September
Parachute Contest (International)—Rome	October
Free Balloon Race—Rome	October
Mapelli Trophy—City and date to be set.	

Successful Trials of the Aveline Automatic Pilot

A young Frenchman, M. Georges Aveline, has invented an automatic stabilizer which promises to go a long way in making flying practically safe. Experiments are now being conducted in France with this stabilizer by the Messageries Aeriennes Company, and a report on tests made on February 14th above Le Bourget in a Farman "Goliath" indicates that the stabilizer is capable of great services in traversing large banks of fog, and in taking off from aerodrames covered in fog. In this latest test several pilots were on board the Goliath, which flew through the fog and emerged into clear air after 1,500 meters altitude, effecting the climb without difficulty and without intervention from the pilot. At this altitude several turns were made, both left hand and right hand. The engines were then throttled down and the machine descended to within 50 meters from the ground, without the intervention of the pilot. During the descent the engines were several times opened up and throttled down, the machine automatically climbing when the engines were opened out and gliding when they were throttled down. Three times during the flight the pilots were changed, the machine flying entirely without pilot during these changes.

The above invention employs a form of the pendulum principle, and part of the device is electric, part pneumatic and part aerodynamic. The pendulum portion, which is only partly to be regarded as a pendulum, consists of an inclinometer in which the fluid is mercury. This mercury is contained in a disc with a narrow circular groove, and serves to make and break an electric contact which operates the valves that admit compressed air to the air cylinder whose pistons actuate the control cables.

A World's Speed Flight

Last autumn M. Sadi Lecointe, the famous French flier, and holder of the world's record for speed in an aeroplane, made an average of 206 miles per hour over four laps, using a Nieuport-Delage fitted with a 300 Hispano-Suiza engine. A little later Mr. J. Herbert James, holder of the British flying record for speed, flying a Gloucestershire Mars I plane, fitted with a 450 h.p. Napier engine, made an effort to beat Lecointe's record, and actually succeeded in doing 212 miles per hour over the lap, though his average for four laps was only just over 196. Since Mr. James' feat there has been much controversy as to whether his machine or the Nieuport-Delage is the fastest in the world. Lecointe's record was made flying both with and against the wind, whereas Mr. James' record on the one lap was made with the wind only. A British newspaper, the South Wales *News*, states that in order to settle this controversy Mr. James challenged M. Lecointe to a series of air races, to take place at Croydon, London, on the occasion of the Royal Aero Club's race meeting on Easter Monday next, for £500 a side, and that M. Lecointe accepted subject to a return race being arranged in France. It is said that a series of flights will be carried out in order to eliminate flukes, and an effort will be made to break the existing world's record. The only possibility of the match falling through lies in the fact that the Nieuport-Delage machine lands at a speed of over 100 miles per hour, and the Croydon airdrome may possibly be too small for a safe landing. The French airman will visit Croydon shortly to inspect the airdrome, and if he is satisfied as to its size the contest will take place.

Testing Aeroplane Steels for Hardness

THERE are a great variety of steels used in the making of aeroplane fittings, each selected for the particular work it is called upon to perform. In selecting the various classes of steel it is necessary to know the hardness of the metal so that it can be properly adapted to its work.

For testing the hardness of metals there are four typical methods. The sclerometer method, introduced by Turner; the scleroscope method more recently invented by Shore; the indentation test adopted by Brinell about 1900; and the drill test, introduced by Keep, a few years earlier.

The principles underlying each of the four methods are briefly as follows:

Turner's Sclerometer

In this form of test a weighted diamond point is drawn, once forward and once backwards, over the smooth surface of the metal to be tested. The hardness number is the weight (in grams) required to produce a standard scratch. The scratch selected is one which is just visible to the naked eye as a dark line on a bright reflecting surface. It is also the scratch which can just be felt with the edge of a quill when the latter is drawn over the smooth surface at right angles to a series of such scratches produced by regularly increasing weights.

Shore's Scleroscope

In this instrument, a small cylinder of steel with a hardened point, is allowed to fall upon the smooth surface of the metal to be tested and the height of the rebound of the hammer is taken as a measure of the hardness. The hammer weighs about 40 grains, the height of the rebound of hardened steel is about 100 on the scale, or about 6 1-4 inches, while the total fall is about 10 inches.

Brinell's Test

In this method, a hardened steel ball is pressed into the smooth surface of the metal so as to make an indentation of a size such as can be conveniently measured under the microscope. The spherical area of the identation being calculated, and the pressure being known, the stress per unit of area when the ball comes to rest is calculated and the hardness number obtained. Within certain limits, the value obtained is independent of the size of the ball and of the amount of pressure.

Keep's Test

In this form of apparatus a standard steel drill is caused to make a definite number of revolutions, while it is pressed with standard force against the specimen to be tested. The hardness is automatically recorded on a diagram on which a dead soft material gives a horizontal line, while a material as hard as the drill itself gives a vertical line, intermediate hardness being represented by the corresponding angle between 0 and 90 degrees.

New Model Club at College Station, Texas

Under the leadership of Staff Sgt. Joseph S. Ott, an enthusiastic group of model flyers are conducting meetings and work classes at College Station, Texas. Permission has been obtained from the College authorities for the use of one of the work shops, where the members meet every Saturday. The entire day is given over to this work exclusively.

Before joining the U. S. Air Service, Sgt. Ott was a member of the Illinois Model Aero Club, his home being in Chicago. This accounts in a way for the progressive spirit shown by the new club which now numbers twenty members. Under his attention models of many varieties are being built and experimented with. In order to give the best samples for the boys to work from, Mr. Ott himself built 12 models as follows: 3 eighteen-inch tractors; 3 twenty-one inch tractors, 1 thirty-inch pusher (which made a flight of 1,200 feet); 2 twenty-one inch tractor seaplanes; 1 thirty-inch single pusher R. O. G. (which climbs about 100 feet and flies 900 feet); 1 twenty-four inch tractor and one scale monoplane.

Although it is two years since building his previous models, Sgt. Ott has designed and built a most interesting type of "Parachute" tractor, which will be described in a later issue of Aerial Age. This model flies about 40 to 50 feet high, and releases a miniature parachute by means of a thread connected to the propeller shaft.

The first model built for one of the school boys, resulting in the idea of forming a club, was a 21-inch R. O. G. tractor, which made two flights of well over 600 feet and nearly always can be depended on for flights of 500 feet. Since the first group of models was built, the number of "stick-type" models constructed in one month by Sgt. Ott totals twenty-one. His pupils have made five successful 18 inch tractors so far.

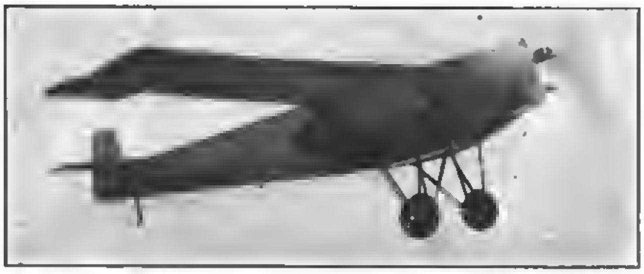
Aviators to Study Ways of Birds High in the Air

Pilots of British commercial aircraft are to be asked to cooperate in solving some of those mysteries of bird life which have so long baffled all efforts of naturalists.

Airmen of the Continental expresses will, it is hoped, throw light on such fascinating subjects as the height at which huge flocks of birds fly when migrating to other lands, and what altitude they are able to attain in flight. They will also help in elucidating the speed of our feathered friends and in unveiling secrets that have baffled poets and scientists for thousands of years.

There are fascinating problems that may now be solved by our flying men. What power is it that enables migrating birds to traverse oceans and continents in a single flight? What connection is there between the weather and migration? After all else, how is it that birds can fly in the darkness of the night without fear of danger?

These are some of the mysteries that may be solved by aerial ornithologists.



A flying scale model of the Fokker FIII monoplane by M. J. Bayhi, as described in Aerial Age last week

RADIO DIGEST

New York Police Combine Radio and Aviation

Keeping fully abreast of the rapid evolution of radio development in these miraculous times of electrical control, the Police Department of the City of New York has in its aviation and radio division a reserve force of limitless potential value as a crime detector and arrester.

It claims to be the most efficient aerial unit in the world and, under the supervision of Rodman Wanamaker, special deputy police commissioner, in command of all reserves, has moved steadily onward from a small beginning to its present high place.

Its commanding officer is Colonel Fiorello H. La Guardia, a soldier with a fine record as an aviator on the battle fronts of the great war and later elected president of the Board of Aldermen of New York.

Its radio instruction is in the efficient hands of Captain Arthur C. Werther.

Inspector John F. Dwyer has had charge of the selection of pilots, and for four years the planes of this force have been flying about the harbor of New York, day and night, and have yet to report the first accident.

Major John F. Brennan is recruiting officer and has been instructed to recruit two more companies of cadets for the corps. His headquarters is at 156 Greenwich Street, Manhattan, where young men, physically sound, are wanted at once to take advantage of this offer of the city for a free education in two modern sciences—radio operating and aviation.

In this reserve aviation corps, in training and in active service, there are now four companies of officers and four of cadets, each company running to about one hundred men each. In the school there are always about two hundred young men in training. The enlistment period is for two years, the city furnishes the uniforms and all other equipment and gives to every cadet who finishes the course a thorough education in the mechanics of the gasoline engine, the science of aviation, piloting an airplane, radio telegraphy and telephony, meterology and kindred subjects. Upon graduation a cadet is equipped to operate any vehicle, either on land, sea or in the air, that uses a gasoline motor for propulsion. He has acquired a trade that is of inestimable value to him, no matter what part of the world he may be in, for there is no part of the civilized world at this time that does not use either one or all of the forces in which he is qualified to operate.

Every cadet is required to master radio in every detail before being assigned to training for flying. He is taught the international radio code from the ground up, until he is qualified to handle the high-powered radio sets employed by the Police Department in actual police work. Here he is taught, first, to send and receive radio messages from the ground, later, he is sent into the air with another cadet pilot and taught to send and receive from an airplane in motion. This instruction he receives directly from the hands of Captain Werther, who is a master of the science and a tactician of high merit.

Besides giving a young man a valuable education in a well-paid trade, this special reserve force educates in another manner. It takes the young man from the street corner, the pool room and the cigar store, where he may be led into temptation to violate the law and make of him a man, one who seeks to enforce the laws rather than to violate them. It teaches him discipline and self control, obedience to superiors and instils in him a pride in his work and in his knowledge of it. Under capable instructors he is taught swimming, boxing, fencing, wrestling, life saving; he plays baseball, handball and other athletic games, and is constantly developing under the instruction and influence of the environment in which others have advanced. From an embryo tough many a young man has been developed in less than the two-years' course into a clean living, healthy citizen of whom the city is proud.

The active personnel of the aviation division and radio corps under command of Colonel La Guardia consists of 102 flight and engineering officers and 160 cadets. It is through the generosity and public spirit of Rodman Wanamaker, Major John Gans, of Staten Island; Captain Theodore L. Bridgeman, Captain Paul Micellit of Sea Gate, and others, that this valuable service has been placed at the call of the metropolis free of cost to the taxpayers. It has cost a vast sum to maintain, but it has produced a corps of men trained in their art to such a degree that they will all be of priceless value to the federal government if they are ever called upon to defend it in time of need, at home or abroad.

Radiophoning from Airplanes

Radiophoning or radiotelegraphing from airplanes calls for the use of a ground wire connection just as much as it does when sending or receiving by wireless from stations on solid earth. Every neophyte knows that electricity travels in circles and that an impulse, once started on its career, keeps on going until it completes its circular course.

Every amateur, when he begins the construction of his home plant makes his ground connection as soon as he has his aerial erected. That completes the circuit and he is ready for the rest. But, suppose he erects his plant in a balloon and turns the bag loose, to drift at will. How is he going to maintain his ground connectioo with that sort of bird? How much worse, many ask, would it be if it were an airplane? How would it be possible to keep in contact with the ground when shooting above it at the rate of a hundred or more miles an hour? It is simple, if you know the sceret.

To Pierre Boucheron, of the Radio Corporation of America, *The Globe Radio Magazine* is indebted for details on this interesting subject of scientific research, given in an interview by Eugene S. Bisbee. In the first place, the air itself acts as part of the "ground" through which the current shoots on its way to and from the airplane equipped with wireless apparatus. The plane carries a trailing wire attached to its transmission set in the cockpit of the fuselage, but this wire doesn't touch the ground at any time, except by possible accident.

Such an accident might happen if the operator neglected to draw in the "ground" wire when near the earth, in which event there might be a catastrophe, for the wire is made of phosphor-bronze stranded cable, and is very strong and flexible. On its end it carries a weight of from one to three pounds or even more, depending upon the length of the trailer and the speed of the plane.

Equipped for radiotelephoning or radiotelegraphing, an airplane carries on its upper wings four insulated standards about a foot high, two on each wing end. These bear the aerial wires from which the messages are sent broadcast. The trailer extends from the body of the ship weighted as explained, for 100 or 150 feet. It is either let out when the 'plane has reached some altitude or is dropped gradually as the ship leaves the earth.

The length of the trailer for "ground" connection depends entirely upon the wave lengths with which the 'plane is operating, the average length being from 300 to 600 metres. From the apparatus in the body of the machine extends a metallic coil, at the end of which is the "ground" wire with its weight on the end. Messages sent to the flying ship from either the earth or another 'plane are caught on the end of the trailer and transmitted to the receivers of the telephone or telegraph on the head of the operator. The messages leave the machine through the aerials and return by way of the "ground" wire, thus completing the necessary circuit for all electric communication.

Radius of communication by airplane is of small importance, except at sea, the uses to which it is put being generally informative to the pilot of weather conditions on the surface. Twenty-five, fifty, or a hundred miles may be negotiated with an ordinary apparatus. This is sufficient to protect a 'plane travelling at the rate of more than a mile a minute or long enough to enable it to avoid danger during foggy weather or darkness.

Greater distances of communication require heavier apparatus, and this is a serious factor in flying. Small sized radio equipment is proportionately weaker than a large and heavy machine, carrying a heavier "ground" wire, and the noise and vibration of the powerful engines of an airplane prevent the operator hearing the weak signals that reach him from great distances. Up to twenty or thirty miles the signals received by an ordinary apparatus are strong enough to be heard distinctly above the roar and the rattle of machinery in the 'plane. Beyond this the electric impulse is too weak to break through the opposing forces and heavier apparatus is necessary for such work.

The vacuum tube is used with the transmission in the radiotelephone and the amplifier in the receiving end materially augments the sound of the signals. Yet the increase of distance operation must depend largely upon the makers of the motors that are used by the 'plane. Lessening of vibration and noise are more important than any other point, for weight in an airplane is a vital factor.

From a ground station an airplane may be directed by radiotelephone to a safe landing during a heavy fog that completely hides the surface of the ground. The pilot calls when he is within half an hour of where he assumes his station to be, say fifty miles away. During the succeeding

Digitized by Google

thirty minutes the messages may be practically continuous and the 'plane directed accurately as it nears.

During the flights between the Florida mainland and the islands of the Bahama group the passenger is constantly in touch by radio with both points and with other flying friends who may be in the air at the time. The "ground" wires trail during the entire flight and are hauled inboard when the ships near the ground. It would never do to rip loose a palm tree from one of those beautiful pearly beaches or anchor the 'plane to a coral reef by inadvertently overloking the "ground" wire and its three-pound weight.

Loop Aerial Cuts Down Interference

How can any one living in an apartment house install a radiophone when the landlord refuses permission to put up an aerial on the roof? This is the most serious question that has confronted the radio fan since the big broadcasting stations commenced sending out a daily program of entertainment.

There are just two answers to this question, and both depend a great deal upon the location of the apartment house, its distance from the broadcasting station and the general conditions surrounding it. One is by means of an indoor aerial and the other by utilizing a so-called "loop" or coil aerial.

The latter is by far the best, because it not only can be used indoors, but it also has the property of cutting out interference to a maximum degree through its peculiar property of only recording signals when one of its edges is pointed directly at the transmitting station.

Its drawback lies in the fact that only a very small amount of current is picked up by it, and consequently it is necessary to use amplification in order to build up that current until it becomes audible in the telephone receivers.

The natural question which now arises in your minds, How can I build a loop aerial? I propose to answer this and then follow it up with a description of the manner in which a loop aerial is used. Before doing so, however, I want to point out that owing to the fact that most broadcasting stations are operating on a 300-meter wave there are many things which prevent us from taking the fullest advantage of present knowledge in connection with a loop, because of the difficulty of handling short waves and their terrific, high frequency.

A loop aerial suitable for reception of short-wave broadcasted music is best made in the following manner: Take two pieces of hard wood, six feet long and about three inches wide. Fasten them together in the middle, so that they are at right angles to each other. Next fasten a piece of hard rubber at each of the four ends, and groove the hard rubber so that it will hold the wire which is to be wound around it.

Upon the frame that you have now constructed it will be necessary to wind four turns of wire. For this purpose you will need seventy feet of 3x16x38 litzendraht cable. It will be necessary for you to wind this wire so that each of the four turns is spaced one-quarter of an inch from the others. This can be controlled by the grooves in the hard rubber.

When you have finished wiring this frame your wire will be square in shape. The two ends of the loop will come together at one corner of the loop. Cut off all the excess wire, leaving about three inches at each end for making connections.

You have now not only an aerial, but also an aerial tuning inductance of a fixed value. If you now place a variable condenser of .001 micro-farad capacity across the two ends of the loop your tuning circuit will be complete, although a little closer tuning can be obtained by placing a small variable inductance in series with the condenser.

The next thing for you to do is to drill a hole through the center of your frame, where the two cross-arms are connected. This should be large enough to carry a spindle which will support the loop on a stand and permit you to turn the loop around in a complete circle. This is very necessary, as you will have to turn the loop around until one of its edges is pointing directly toward the station you wish to listen to.

Use Regular Amplifier

After you have done this you will have to connect a vacuum tube detector and two stages of audio-frequency amplification to the two ends of the loop where you have the condenser joined across. The regular cabinet form of detector and two-stage amplifier can be used for this purpose.

For persons living within twenty-five miles of the broadcasting station, it will probably be found that satisfactory results can be obtained with a loop aerial using only a vacuum tube detector and without amplification, but local conditions will determine this to a great extent.

There isn't any question about the advantages of a loop aerial. It eliminates all interference, except that which emanates from some point in a direct line with the transmitting station. It also eliminates a great deal of static.

Where it is impossible to put up a loop because of the amount of amplification needed results may be obtained by using an indoor aerial. This can be done by laying 150 feet of No. 18 covered bell wire around the picture molding of a room and joining one end to the instruments where the outdoor aerial is usually attached. In this type of aerial a ground connection will be necessary, which, by the way, is not necessary with a loop aerial.

Reception by means of a loop aerial will be greatly improved as soon as effective means have been discovered for the application of radio frequency amplification on short waves. Radio amplification is very simple with very long waves, but no great success has yet been obtained with short waves. When it has it will be possible to use an indoor loop aerial almost anywhere in the country.

—*New York Tribune.*

New Charging Battery Works As You Sleep

Radio, the new national pastime, which already numbers its disciples by the hundreds of thousands, is stimulating immensely the popular interest in electricity.

Itself an electrical manifestation, it requires certain electrical equipment, and in some cases this equipment is arousing radio enthusiasts to the unique value of electricity to mankind in general, especially to home dwellers.

Undoubtedly this opening of the eyes, so to speak, begins through the necessity of charging the storage batteries used in radio sets. These batteries have to be recharged frequently, and if the radio operator was compelled to take the battery each time to a battery service station it would mean considerable trouble, expense and time.

Double Purpose

Hence the popularity among radio folk of gas-filled rectifiers for charging these batteries. And if the radio amateur is also an automobile owner, the rectifier has for him a double usefulness, since it will recharge the starting and lighting battery in his car as well as the radio battery of his receiving set.

To many radio followers this gives a big importance to the function of electricity in the home—a function that is many-sided.

Rectifiers originally devised for other uses are now finding new application in the radio field. The Tungar battery charger is a type of gas-filled rectifier in use for some years to recharge automobile batteries, and now developed to serve a similar purpose in recharging radio batteries.

This rectifier is made in various sizes, from small outfits intended for railway signal work up to large service station sets which will charge ten or twenty automobile batteries simultaneously. For radio work, however, the small, portable type in 2-ampere and 5-ampere capacities is the best for the purpose.

Familiar System

The electrical theory on which they operate is similar to that of the two-element vacuum tube with which the average radio fan is familiar. The essential part is a bulb, or glass tube, which contains a cathode and an anode. The cathode is a short tungsten filament and the anode —or, in terms of radio, the "plate"—is a graphite disc.

After being exhausted of all air, the bulb is filled with argon, an inert gas. This is the chief difference between the Tungar bulb and other two-element bulbs, such as the Flemming valve and the kenetron.

The vacuum tube depends for operation on the emission from an incandescent filament of small particles of negative electricity called electrons. The electrons themselves are the only current carriers, so that consequently the tube will rectify only a small amount of current at a comparatively high voltage.

In the case of the Tungar bulb, the electrons emitted by the heated filament ionize the gas, thereby making it conductive. This ionized gas acts as the principal current carrier, with the result that the bulb operates with a very much lower voltage drop (5 to 10 volts) and is capable of passing a current of several amperes.

The action of the bulb is similar to that of a one-way valve. During one-half of the cycle, electric current flows through the bulb from anode to cathode; that is, from the "plate" to the filament. But during the other half of the cycle, no current can flow. Hence the term "half wave" rectifier.

The 2-ampere Tungar will charge a 6-volt battery at two amperes, or a 12-volt battery at one ampere. The 5-ampere outfit will charge a 6-volt, 3-cell battery at five amperes, or a 12-volt, 6-cell battery at three amperes.

The Tungar is a product of the well-known research laboratories of the General Electric Company. Its use will enable the radio amateur to keep his receiving station always active. An inactive station is the one thing the radio fan abhors. If his set is out of commission for several days, because his battery has run down, he knows that he may miss some of the best air features of the season.

ALLEN E. PECK
Patent Attorney
Pacific Bldg., Washington, D. C.

COMMERCIAL PILOT AND MECHANIC wishes position with private party or firm. Will go anywhere. Best references. Address Hugh C. Robbins, Lock Box No. 6, Williamsburg, Ohio.

MUST SELL MY JENNIE, new OX5 motor, run only few hours. Little work will complete ship. Sell for $450.00. Carl W. Mueller, 5680 Oak Grove Ave., Oakland, California.

FOR SALE—Three place Tractor, almost new and in A1 condition. Extra strongly built and roomy. Without motor or fitted with new Hispano-Suiza. Further information on application. Address Box 665, c/o AERIAL AGE WEEKLY, 5942 Grand Central Terminal, New York City.

MECHANIC CAPABLE OF RIGGING and re-building F boat. Must have commercial experience and thorough knowledge of Hall Scott motor. Capable of functioning as executive. State salary expected. J. M. Corbett, Central Square, Somerville, Mass.

FOR SALE—Canuck ship perfect shape. Motor just overhauled. The best buy ever offered for $975.00. Tobener Bros., 604 East 15th St., Kansas City, Mo.

OX5 CURTISS 8 cylinder motor just over-hauled. Perfect shape. Brand new magneto and propeller. First $185.00 takes it. J. C. Shumway, 1607 McGee St., Kansas City, Mo.

FOR SALE OR TRADE—New, never flown, three passenger DeHavilland Six with Curtiss OX5 motor complete all instruments. Make offer. Address Box 653, c/o AERIAL AGE WEEKLY, 5942 Grand Central Terminal, New York City.

AVRO-CLERGET FOR SALE, new license paid. Just set up ready to fly, near New York. A bargain for quick buyer at $1,050.00 Address Box 661, care of Aerial Age Weekly, 5942 Grand Central Terminal, New York City.

THOROUGH PRIVATE FLYING INSTRUC-tion on Long Island. A few pupils accepted at exceptional rates. Address Box 662, care of Aerial Age Weekly, 5942 Grand Central Terminal, New York City.

What Is Your Problem In Commercial Aviation?

GETTING STARTED?	All right, we have a stock of Airplanes and Motors ready to fly.
KEEPING GOING?	We can help you hacause we are the largest commercial aviation supply house in tha country.
SERVICE?	Johnson Service means good service, including a modern equipped fiying fiald and shop.
INFORMATION?	Our information department is at your service free of charge.
PRICES?	Lowest prices consistent with hest material.
GUARANTEE?	Our customers must he satisfied always, or their monay refunded.

Let us solve your preblems in commercial aviation. Write us first and avoid costly delays. Our new catalog mailed on request.

A FEW SUGGESTIONS TO MAKE YOUR PLANE LOOK SNAPPY:

New flottorp propeller, copper tipped $30.00
New radiators, Curtiss or Standard 20.00
New upholstered wicker seats 3.00
New side cowl or cock-pit cowl Curtiss or Standard 15.00
New streamlined wheels, 26x4 .... 10.00
New Goodyear cord tires, 26x4 .... 10.00
New fuselage covers, ready to put on, Curtiss or Standard $15.00
New wind shields 2.00
New shock absorbers, per foot .... .00
New safety belts, American type 3.00
New center section with fittings, for Standard 10.00
New hose connections, all types .... .10
New hose clamps, all sizes ....$ .10
New Hartzell propeller, new design, brass tipped 60.00
New Warner tachometer with shaft 6.00
New thermometer, 15 ft. tube 7.00
New altimeters, 20,000 foot, luminous dial 10.00

(Continued from page 123)

miles across deserts and plains and concentrated in any troublous spot without the fatigue of forced marches. Thus, before a savage enemy expects attack he can be pounced upon by a powerfully and perfectly fresh force."

A layman can readily understand the great military power of modern air forces in the cases cited above.

Foreigners have not been first, nor are they alone, in recognizing the vital importance of air forces. Ten years ago Admiral Fiske declared that we could best defend the Philippines and our other foreign possessions by air forces. And Admiral Simms has recently asserted: "The command of the air means the command of the surface, whether it be sea or land. The experiment of sinking the Ostfriesland by aeroplane bombs proves that if our coast is protected by aeroplanes no ships can reach our shores or land troops."

Thus, the best authorities at home and abroad are of one mind—that air power will dominate in future war.

In the meantime what are we doing? Actions speak louder than words. In truth, it may be said that the United States is dawdling. The aviation bureaus of the army and navy are doing all in their power with the limited and crude facilities they possess, but their hands are more or less tied. Appropriations for aviation are insufficient and conservatism continues to place hurdles in its path.

Moreover, legislation and laws for the encouragement and regulation of civil aviation are held up. The Wadsworth-Hicks bill for Federal control of aeronautics, after passing the Senate, is being mangled, if not strangled, in the House by flaw-pickers and all sorts of seemingly jealous personal or bureaucratic influences. And little legal minds with states rights, personal rights and property rights preying upon them in this modern age, are supporting Farmer Brown in his claim that he owns all the air between his cow pasture and the moon, and that no trespassing aviator can fly through and breathe his oxygen without paying for it by the cubic inch!

Thus, while aviators are flying all over Europe, and when we are told that "a night air line between London and Paris will be in operation soon to carry the mails," when we are assured that "sleeping car aeroplanes will soon be in operation for tired business men who must cross the Channel quickly"—while all these advances are being made abroad the government of the United States appears to be asleep at the switch.

The need of prompt and intelligent action is imperative. Aviation, both in peace and in war, is already a dominating force. —Quarterdeck, in the N. Y. Tribune.

Learn *to* Fly

Aviation is making such strides that it needs more men right now

You Can Learn To Fly

I can teach you how to become a successful pilot in a short time. My course is so arranged that you get only the things you need to make you a good aviator.

The Diggins Extension Course

is up-to-date, teaches you what you must know to become an expert flyer. This course is written by competent instructors right on my flying field. It is kept right up to the minute—all new developments in aviation are included. That is why it is recognised as the most complete and practical course offered today. My course saves you time and money because it prepares you at home so that you are ready to begin flying the day you arrive at the flying school.

Superior Points of the Diggins School

1. The Diggins school is the oldest, largest and most complete commercial aviation school in America.
2. The Diggins school is located in Chicago, the center of Aviation.
3. Living quarters and free employment service are maintained for students.
4. Diggins guarantees to make you a pilot.
5. Diggins' pilots get top notch salaries.
6. References, any aero club in America.

WRITE TODAY Write today for the new Diggins beautifully illustrated catalog.

The Ralph C. Diggins School of Aeronautics

Can *You* Fly?

The very fact that you have this publication in hand is evidence that you are interested in aviation.

The question then is *Can You Fly?* If you cannot fly, but have ever entertained a desire to do so, this message should be of intense interest to you.

Why Not Learn?

Aviation is here to stay—and it has a future even brighter than many imagine. Already, greater strides are being made than most people are aware. Our training of Pilots, which was discontinued on America's entrance into the late war, has been resumed—and with facilities such as were never before known.

SEND FOR BOOKLET IF INTERESTED

If the above thoughts appeal to you, address our School Division for further information. There will be no obligation at all and we have a complete new booklet on this particular subject, which is free for the asking. Even if you should decide you would not care for it for yourself, why not send for it for someone else? Many likely young men might be glad to know of just such an opportunity as this and would appreciate your putting them in touch with it.

Farman

PERFORMANCE

THE RECORD for both the greatest number of passengers carried and the greatest tonnage of express transported on the Paris-London Line—the busiest air-route in the World—is held by the 14-Passenger Farman "Goliaths."

This is the *Fourth Year* of regular Farman Air Transportation Service.

Farman "Goliath" Airlines carry capacity loads — the cream of the business — wherever there is competition in Aerial Transportation.

Shouldn't such excellent service be available today in the United States?

WALLACE KELLETT CO., Inc.

WIDENER BUILDING **PHILADELPHIA, PA.**

Pilots!

Pilots of today are making aeronautical history just as in the early days of Curtiss, the Wrights, Ely, Hoxey, Brookins, Beechey and others.

Now, as then, the most successful Pilots and Flying Organizations are using Curtiss Aeroplanes.

Because good pilots know that Curtiss Aeroplanes scientifically embody the requirements of successful flight—

RELIABILITY
STRENGTH
PERFORMANCE
ECONOMY
COMFORT

Curtiss service which covers the continent is also an important factor in the selection of Curtiss Aeroplanes by America's best known Pilots, Flying Schools, Aerial Photo Companies and Aerial Transport Companies.

USED JN'S FROM $650 UP

Watch this space for list of America's best and most successful flying organizations. Of course they use and sell Curtiss Aeroplanes.

Amundsen's Aeroplanes

ROALD AMUNDSEN calculates that his drift on the Maude from Point Barrow, or thereabouts, to Norway by way of the North Pole will take five years. The distance from Point Barrow to North Cape, Norway, is about 2,500 miles. Captain Amundsen has just started in a metal monoplane for Seattle, which is some 3,000 miles from New York. It will be a flight with stops, but the distance could be made by daylight and a full moon in about thirty hours. The explorer naturally wants to learn how his new ship is sailed, for if he is to stand where Peary made his North Pole obserservations on April 6, 1909, the monoplane may be very useful. The drifting Maude should eventually shake herself free of the ice and emerge into blue water somewhere off the coast of Norway, unless the pack destroys her, but the chances of her passing very near the Pole are not bright. At some point the explorer would probably have to leave her and march or fly in the direction of the Pole.

There might be a risk in seeking the ship after a "dash" toward the Pole if it were necessary to depend upon dog sleds. The Maude might not move very fast, but if the explorer and his picked companions were absent from her for weeks there would be danger of missing her altogether. Polar weather is treacherous. It is easy to go wrong on the ice expanse; moreover, leads or open water may occur when explorers are at the end of their resources. Captain Amundsen wisely decided to take two aeroplanes with him, one for important flight work and another for scouting. The big metal plane has already flown in the Arctic Circle at very low temperatures. Both machines should be great time-savers if the Maude's drift carries her within quick flying distance of the Pole. It should be comparatively easy to pick her up after an excursion in any direction.

Admiral Peary foresaw the use of the aeroplane for Arctic exploration as long ago as 1912. In his book "The Secrets of Polar Travel" (1917), he said: "Five years ago at the annual dinner of the Explorers' Club I ventured the prophecy that in a few years the polar regions would be reconnoitered and explored through the air." He made his "drive" for the Pole from Cape Columbia on the northern coast of Grant Land, which is less than 500 miles south. He went on to say:

"From Cape Columbia it is less than 1,400 miles in a straight line directly across and over the Pole to Cape Chelyuskin on the Siberian coast, the most northern point of Eurasia. To Wrangell Island across Crocker Island and the entirely unexplored region between the Pole and Bering Strait it is about 1,500 miles. From Cape Columbia to Spitzbergen it is 900 miles, to Franz Josef Land less than 1,000 miles and to Point Barrow about 1,400 miles.

It is relevant to note that the metal monoplane acquired by Captain Amundsen has kept the air for more than twenty-six hours and has already flown from Mineola to Fort Norman in the Arctic Circle, 6,000 miles. It is conceivable that under favorable conditions this plane could be flown from Point Barrow to North Cape, Norway, with a stop in the neighborhood of the Pole, but Raold Amundsen is too experienced an explorer to face such desperate risks. The drift by the route the Melville-Bryant cask No. 2 was supposed to take is theoretically both safe and sure, and the North Pole can best be reached by an aeroplane in the hands of those who understand its limitations.—*Editorial in N. Y. Times.*

Air Transport in Europe

SINCE the war political and physical handicaps to railway travel in Europe have been tantamount to discrimination in favor of air transport, which knows neither the limitations of international boundaries nor the time consuming factor of overworked and in many cases decrepit rolling stock. The result of this unintentional though none the less real subvention of air transport has been the development, especially in France, of commercial flying services that already are in a fair way to rival the fast railway trains for passenger and express traffic.

The French Air Ministry reports that the distance covered by French commercial planes alone in 1921 was nearly 2,000,000 miles. Flights by these planes numbered 6,000, passengers carried were 10,330, merchandise freight weighed 366,278 pounds and postal matter 20,758 pounds. The figures for passengers and cargoes are three times as large as those of 1920 and ten times those of 1919.

There are eight companies in France operating air routes, which radiate in all directions from Paris. It is now possible to take off from the French metropolis in a plane of any one of the eight companies any day in the week and reach London, Amsterdam, Prague, Warsaw, Nice, Barcelona, Alicante, Malaga, Bilbao or Havre. In most cases the return trip can be made by regular service in a single day.

In 1922 the subsidy for the French commercial air service is 41,382,000 francs, or about $4,000,000. England comes second

THE NEWS OF THE WEEK

National Flying Meet

New York—More than sixty aeroplanes have already been entered in the first of the national flying meets sanctioned by the Aero Club of America and the Aeronautical Chamber of Commerce which will be held at Curtiss Field, Garden City, L. I., N. Y., Sunday, April 30, it was announced.

The Rotary Club of New York is supporting the event which is designed to show the progress made in the development of American commercial aircraft during the last six months. Many new types will be flown in the various exhibitions and contests, which include races, speed trials, parachute jumping, efficiency and performance tests and passenger carrying. The Rotarians will have a special section reserved for them and their friends. It is the first of a series of such flying meets to be held throughout the United States this year, to demonstrate to the business and professional public the peculiar qualities of the flying machine in speed and economic operation.

In its announcement of the flying meet, the Aeronautical Chamber of Commerce points out that "while 275,000 persons traveled by air in this country last year—by far a larger number than in all Europe—the aeroplane is a difficult machine with which to demonstrate. Instead of driving up to his front door and inviting the business or professional man to take a ride, as is the custom with the motor car salesman, the man who would demonstrate an aeroplane must first get his audience out to the flying field where he can provide a close-up of the machines in actual operation." Through courtesy of the Curtiss Aeroplane & Motor Corporation, their field has been made available for the New York meet, which is the first of its kind to be held.

"With the co-operation of the Rotary Club and other organizations," reads the announcement, "it is hoped to put before the traveling and transportation public this year free aerial exhibitions which, because of the large scale with which they are presented, can not help but convince the average person that flying is a practical method of travel. It is believed that the meet at Curtiss Field April 30th will be as instructive as it is entertaining."

Two Airplane Hangars for Hartford

Hartford, Conn.—Two mail service aeroplane hangars offered to Hartford by the United States Post Office Department have been accepted by the Hartford Aviation Commission. The hangars will accommodate six planes and will be set up on the municipal aviation field here. Their erection is expected to be completed in May, and would facilitate a possible air mail service to New York and Boston in the future. The hangars were offered for a fraction of their cost, it was stated, to encourage aviation here.

National Advisory Committee for Aeronautics Meets April 20

Washington — A program for aeronautical research and development for the coming year will be considered by the members of the National Advisory Committee for Aeronautics at its semi-annual meeting, to be held in the Navy Building on Thursday afternoon, April 20.

The Committee, which is headed by Dr. Chas. D Walcott, is composed of independent and Governmental scientists and engineers. The scientific research and development undertaken during the past year in both civil and military aviation will be reviewed. Problems of aeroplane wing design, new developments in aeronautical engines, methods of testing aeroplanes, wings and parts, airship studies, lifting gases, aerial routes, the air mail service, and problems for the advancement of commercial aviation are among the subjects to be discussed.

Dr. Joseph S. Ames, Chairman of the Executive Committee, will outline the future plans of the committee with a view to placing America "foremost" in the development of aviation, as President Harding has recommended to Congress.

Dr. S. W. Stratton, Secretary of the Committee, will render a report on organization and the committee's activities in placing technical information on aeronautics where it will do the most good.

The development of a new type of aircraft engine with a view of eliminating the fire hazard by the use of heavy fuel oil in place of gasoline, will be among the subjects discussed. Special studies and tests of a new high-speed aeroplane wing, believed to be of great value in the interests of military scout planes, will be recounted by Dr. Ames. The allocation of the annual budget for special research problems will be discussed by the members.

During the sessions, Orville Wright and John F. Hayford, members of the Committee, will make a trip to the laboratory of the Committee at Langley Field to inspect the laboratory and make suggestions in connection with the tests and experiments contemplated.

Paul Henderson, the new Second Assistant Postmaster-General, who has charge of the Air Mail Service, has been invited to attend the meeting in view of his interests in aviation.

As an independent branch of the Government, the Committee holds itself in readiness to serve the President, the Congress and the executive departments in connection with aeronautical problems. The study of governmental aeronautical activities, recommendations for action under the International Air Navigation Convention concerning the development and regulation of civil aviation, and encouraging aeronautical engineering are among the duties of the Committee.

The members of the Committee expected to attend the meeting are:

Dr. Chas. D Walcott, of the Smithsonian Institution, Chairman.

Dr. S. W. Stratton, of the Bureau of Standards, Secretary.

Dr. Joseph S. Ames, of Johns Hopkins University, Baltimore, Md., Chairman of the Executive Committee.

Maj. Thurman H. Bane, Army Air Service, Dayton, O.

Dr. Wm. F. Durand, Leland Stanford Junior University, Calif.

Prof. John F. Hayford, Northwestern University, Evanston, Ill.

Prof. Charles F. Marvin, Chief of the Weather Bureau, Washington, D. C.

Rear Admiral Wm. A. Moffett, Chief of Naval Bureau of Aeronautics, Washington, D. C.

Maj.-Gen. Mason M. Patrick, Chief of the Army Air Service, Washington, D. C.

Dr. Michael I. Pupin, Columbia University, New York City.

Rear Admiral D. W. Taylor, Chief Constructor, U. S. Navy.

Orville Wright, Dayton, Ohio.

Spokane News

Spokane, Wash.—Raymond Small and George Stonebraker, of Lewiston, Idaho, are negotiating for airplanes to open an air route from Lewiston via Grangeville to the Chamberlain basin on the middle fork of Salmon river, for the accommodation of hunters who desire to visit that game region.

The distance between Lewiston and the basin is about 100 miles, and under present conditions the trip involves seven days of toil by horseback and pack saddle. Fuel for the final leg of the flight will be loaded at Grangeville.

To negotiate the trip planes will require to attain a height of 10,000 feet on leaving Grangeville, for in case of trouble the plane must return to Grangeville or glide into the basin.

It is planned to cross the Salmon river brakes at an altitude of 5,000 feet. The Salmon river gorge is about 9,000 feet. Passengers will be able to look down to the canyon 14,000 feet below. Chamberlain basin includes about 500 acres of meadow lands, affording good landings.

By a contract signed up with the Curtiss Airplane Corporation the United States Aircraft Company of this city is authorized agent of the Curtiss firm, and entitled to sell ships throughout the northwest, according to announcement made by C. H. Messer, head of the local concern.

"We will immediately put in a complete stock of parts for Curtiss ships and motors, as well as carrying the stock of Standard ship parts, as we do at present," Mr. Messer said. "This will give us the agency for ships and parts for the entire northwest. We will carry complete parts for every ship now flying in the district."

COMING AERONAUTICAL EVENTS

AMERICAN

- Apr. 30.—Spring Show and Opening Meet, Curtiss Field, Mineola, L. I.
- May —National Balloon Race.
- Sept. 4 (*about*).—Detroit Aerial Water Derby, Detroit. (Curtiss Marine Flying Trophy Competition.)
- Sept. 15 (*about*).—Detroit Aerial Derby, Detroit. (Pulitzer Trophy Race.)
- Sept. 30.—First Annual Interservice Championship Meet. (In preparation.)

FOREIGN

- Aug. 1 (*about*).—Coupe Jacques Schneider. (Seaplane speed race.) Italy, probably Venice.
- Aug. 6.—Gordon Bennett Balloon Race, Geneva, Switzerland.
- Oct. 1.—Coupe Henri Deutsch de la Meurthe. (Aeroplane speed race.) France. American elimination trials, if required, to be held about Aug. 15, at Mitchel Field, L. I.

The AIRCRAFT TRADE REVIEW

American Aeronautical Developments

Washington.—Some of the achievements in the progress of aviation in America will be revealed for the first time by Dr. Joseph S. Ames, of the National Advisory Committee for Aeronautics, in an illustrated public address in the New Building of the U. S. National Museum at 2:45 P. M., Tuesday, April 25.

Dr. Ames will review some of the remarkable scientific achievements of the Committee's laboratory at Langley Field, Va., and will describe and explain the operation of newly developed instruments for the determination of the characteristics of aeroplanes in flight, which will enable the designer and builder to design planes of particular performance characteristics, such as high speed maneuverability. New instruments developed at the Committee's laboratory indicate the pressure distribution over the surface of an aeroplane in flight including the control surfaces, the results of which will have an important bearing on the safety factors used in the construction of aeroplanes.

Two entirely new methods of determining aerodynamic properties of aeroplane wings such as lift and resistance, will be discussed by Dr. Ames: They are the trailing wing method and a new form of wind tunnel. Instruments for determining the stresses produced on aeroplanes when violently maneuvered, as in spins, barrel rolls, and loops will be shown and the results discussed.

Members of Congress interested in aeronautics have been invited to listen to Dr. Ames' remarks through the courtesy of the National Academy of Sciences, under whose auspices his address will be given.

Personal Par

Laureston Craig, former aviation instructor, and a former member of the advertising department of the New York Commercial, will sail on the steamer Finland, April 22nd for Russia, where he will be assigned to child feeding work of the American Relief Administration.

Mr. Craig, who is a native of Island Falls, Maine, was a member of the class of 1919 at Colby College, but he interrupted his studies to cnlist in the U. S. Air Service. Serving at Dorr and Barren Fields, he was made an instructor in aviation, and was later on duty at Carlstrom and Post Fields. Following his discharge from the army he resumed his studies at Colby College, graduating with the class of 1920. Since that time he has been in business in New York City.

National Balloon Race

The Aero Club of America announces that the American National Balloon Race will be held this year from Milwaukee on May 31, 1922, under the auspices of the Aero Club of Wisconsin. The following prizes are offered: 1st $1,000, 2nd $800, 3rd $600, 4th $300, 5th $200, 6th $100.

In addition to the above, $100 will be paid toward the expenses of each contestant who actually starts. The entry fee (for civilians) is $50 payable to the Aero Club of Wisconsin, to be returned when the contestant arrives at the starting field with his complete equipment.

The starting field (the Milwaukee Ball Park) is limited to approximately ten balloons, and applications for entry will be accepted in the order of their priority. It is expected that the Army will have three entries and the Navy three.

The three leading teams at the finish will in all probability be chosen to represent this country in the International Gordon Bennett Race which starts from Geneva, Switzerland, on August 6th.

All applications and requests for information should be addressed to the Aero Club of Wisconsin, 208 University Building, Milwaukee, Wis.

The Drag of C Class Airship Hull With Varying Length of Cylindrical Midships

A model of the C class airship hull, when severed at its major section and provided with a cylindric mid-body of variable length, had its air resistance increased about in proportion to the length of the mid-body up to 3 diameters, and in about the manner to be expected from the increase of skin friction on this variable length. For greater length the drag increased less and less rapidly.

As usual for such models, the drag for any fixed length, at 20 to 60 miles an hour, is accurately of the parabolic form $R V^n$ and hence the drag coefficient is of the hyperbolic form $C V^{n-2}$, where n is lightly less than 2.

The variation of C with length is stated in the conclusion.

A copy of Report No. 138 by A. F. Zahm, R. H. Smith and G. C. Hill, may be obtained upon request from the National Advisory Committee for Aeronautics, Washington, D. C.

Michigan Airways Organized

The Michigan Airways has been organized in East Lansing, Michigan, to engage in aerial photography, aerial advertising and exhibition flying. Arthur J. Davis is president of the company and Talbert Abrams, vice-president. Mr. Davis was instructor at Kelly Field during the war and Mr. Abrams was associated with the Curtiss Company at Buffalo, New York, prior to the war and served in the Marine Corps during the war.

Localized Radio Landing Signals for Aeroplanes

Radio direction finders and other devices have been in use for some time to assist airplanes in landing during the night, fog, or at other times of poor visibility. The most usual method of employing radio for this purpose is to transmit from any ordinary elevated antenna at the landing field radio signals which are received on a direction finder carried by the airplane. Sucn a method gives the direction of the landing field but does not tell accurately the distance from the plane to the field.

Several years ago the Bureau of Standards was called upon to develop a method to assist airplanes in accurately locating the landing field when the airplane was quite close at hand. A method was desired which would give a signal heard over a comparatively large area when the airplane was at a high altitude but would be localized within a small area when the plane was near the ground. A method employing a large horizontal coil tuned to 500 cycles was tried but did not prove satisfactory. The use of radio frequency waves was, therefore, undertaken and two horizontal coils, one above the other, with current flowing in opposite directions, were used. A fairly high radio frequency, such as 300 kilo-cycles, was employed in this case.

A calculation was made which indicated that the signals radiated from the 2 coils would be the strongest for an airplane flying in a given horizontal plane whenever the airplane was within a comparatively small ring-shaped area located above the landing field. The results of these calculations were verified in practice.

The Bureau of Standards has just published a paper giving the theory of the radiation from an antenna consisting of 2 horizontal coils such as that described above. The area within which the signal is heard and the point at which it is most intense are discussed. The results of these investigations are given in Bureau of Standards Scientific Paper No. 431, "The Field Radiated from Two Horizontal Coils," which may be obtained from the Superintendent of Documents, Government Printing Office, Washington, D. C., at 5 cents per copy.

First Pursuit Group to Hold Meet

The First Group (Pursuit), now stationed at Ellington Field, will celebrate its Organization Day (May 5th), this year, with flying and athletic activities on May 5th and 6th. This celebration will be worth while to induce anyone interested in aviation to travel across the country to witness it.

An invitation is extended by the First Group (Pursuit) to all persons interested in air activities to be present at Ellington Field, Houston, Texas, on those dates.

The following events will be a part of the program:

1. Flying: Aeroplane races of every description; exhibition of aerial combat, aerial acrobatics, gunnery, bombing and acrobatic formation flying; exhibition of various types of aeroplanes, motors, maintenance equipment, and flying training equipment.

2. *Athletics*: Boxing bouts, baseball games (Ellington Field vs. Kelly Field), volley ball championship game, track and field meet.

It is especially desired that all Ex-Service Pilots be present as every Air Service Station in this vicinity will have a large delegation at Ellington Field, and the event will be a reunion and gathering of Air Service friends.

REACHING THE STARS BY AEROPLANE

Being the Tale of Movie Luminaries Who Have Succumbed to the Lure of "Giving 'er the Gun!"

By CHARLES L. GARTNER

ONE of the dreams of the average movie fan is to gain an interview with his or her favorite star; to sit down in a quiet little corner and ask all the intimate questions he or she has wanted to for a long time. But, to the layman, most of the screen lights are harder to reach than a bank president during a Bolshevik riot. Only in exceptional cases does the admirer of the silver sheet get a chance to get in personal contact with the luminaries of the silent drama.

One of the surest ways, figuratively speaking, of getting the ear of a star, is to mention aeroplanes. Almost the entire movie colony in Hollywood is aeroplane struck. Directors, stars, scenario writers, authors and even cameramen are aviation enthusiasts, many of them being licensed pilots.

Betty Compson, star in Paramount Pictures

What may come as somewhat of a surprise to many movie fans is that Mary Miles Minter, one of the youngest and best known of the ingénues on the screen today, has qualified for a license as pilot. Miss Minter successfully passed the test over a year ago but parental objection has prevented her from taking advantage of her pilot's card. She is not permitted to ascend with the controls in her own hands.

Cecil B. DeMille, director-general of the Famous Players-Lasky Corporation, is one of the pioneers of aviation in the motion picture center of the world. Mr. DeMille, for a long time, was part owner of a passenger aeroplane company which made regular trips from Hollywood to nearby cities. He is also one of the most prominent figures in aviation on the coast and often takes his "bus" out for a few dips and tail spins in order to forget the cares of his office. Mr. DeMille asserts that there is no better tonic in the world for "that tired feeling."

Dorothy Dalton, star in Paramount Pictures, is another ardent advocate of the "travel by aeroplane" slogan. Miss Dalton's specialty is hydroplaning, for she much prefers the water route than the solid earth below.

A more recent addition to the ranks of the flying stars is Betty Compson, the girl of "The Miracle Man" fame. Although kept extremely busy out on the coast Miss Compson manages to find an occasional hour or so every few days to devote to the thrills of flying. Miss Compson has yet to win her pilot's license but hopes to secure the coveted card before she is many months older.

But perhaps the most enthusiastic, for aviation, of the movie people on the coast is Jeanie Macpherson, scenario writer for Paramount Pictures. Miss Macpherson has been flying for at least three years and is one of the most prominent aviatrices in California. She numbers among her acquaintances many of America's leading aviators, and she has participated in more "stunt" and "circus" flying than any other person connected with the motion pictures who is not paid for risking his or her neck. She has made a number of trips with Ormi Locklear, world famous "stunt" man, from whom she learned many of the finer points of the art of flying. The news of Locklear's tragic death some time ago came as a genuine shock to her.

Speaking of Locklear, Miss Macpherson said, "Ormi Locklear was, to my mind,

Jeanie Macpherson, scenario writer for Paramount Pictures

a natural flyer. His judgment in the matter of height, and in that of keeping the plane level, was uncanny. I remember one trip I took with him out on the coast in which he took me out to sea. We unexpectedly ran into a dense fog. I was frightened to death, as we could hardly see each other, but Locklear, without even bothering to consult his instruments, kept right on going, and when he thought we had gone far enough he turned his machine and headed back again.

"If I had had the machine there is no doubt that I would have been flying for Canada, Mexico or the open sea, but in a short time we were out of the mist and to my great surprise, and greater relief, found that we were headed straight for our own landing place. I believe Locklear, with that sixth sense of his, could fly his 'boat' in the dead of night, without a light to guide him, and get through safely. That's why I can't understand some of the reports which were circulated about Locklear losing control of his machine on a difficult loop."

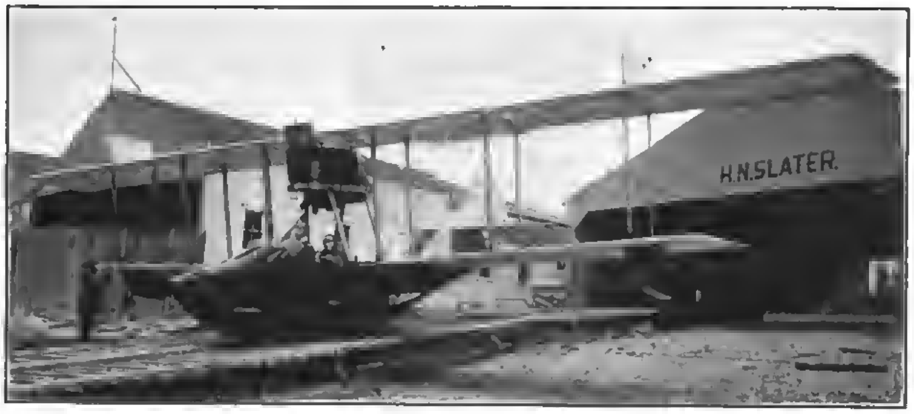
Eddie Rickenhacker, America's famous ace, is another close friend of Miss Macpherson's. In fact, Rickenhacker was Miss Macpherson's tutor at one time.

The writer knows of a little incident that shows Miss Macpherson's love for flying. Some time ago Miss Macpherson came East preparatory to sailing for

Gloria Swanson and C. B. DeMille witnessing an aerial circus

Digitized by Google

Europe for a well deserved vacation. As is the case with all motion picture celebrities of the motion picture world, a great deal of Miss Macpherson's time during her short stay in New York City was taken up by interviewers from newspapers and magazines. One interviewer, who had been in the flying corps overseas, had been pumping Miss Macpherson on the cut and dried subject of scenario writing. The conversation was lagging when the gentleman in question suddenly looked at his watch and mentioned the fact that he would have to leave as he had an appointment with some one at the Aero Club. That proved to be the opening wedge for a conversation that lasted far beyond Miss Macpherson's dinner hour and incidentally, long past the time set for the appointment at the Aero Club. Needless to say, the subject discussed was aeroplanes and, much to the surprise of the ex-service man, Miss Macpherson spoke fluently upon the respective merits of aeroplane motors of foreign and domestic make. The writer can testify to the above fact, for he had to sit through many weary—to him—minutes of technical descriptions of the Hipsano-Suiza, Liberty, etc. Than which, to the layman, there is nothing more complex.



Dorothy Dalton, star in Paramount Pictures

AEROPLANE WILL CARRY SUSPENDED WING IN TEST

A FULL-SIZED aeroplane wing suspended below an aeroplane in high speed flight will shortly be tested at the Langley Field Laboratory of the National Advisory Committe for Aeronautics. This will be the first time that a real wing has been tested in actual flight, and is the final step of developing a new method of testing the performance and lifting properties of aeroplane wings.

This new method was developed by the National Advisory Committee for Aeronautics, which is composed of 12 American scientists who devote a large part of their time to the solution of aeronautical problems—without compensation. The method recently demonstrated successfully with model wings in air flights, consists in carrying the wing to be tested below an aeroplane in flight and, by means of suspension apparatus and recording instruments, to measure the forces of lift and resistance directly from the wing.

A complete aeroplane cannot be tested in flight as there is no means nor method of measuring the factors desired; there is nothing to suspend the plane from and its lift or pull cannot be measured by instruments carried on the plane itself.

Heretofore tests of new wings have been made in one of the following manners: Years ago, Dr. S. P. Langley used a whirling arm which carried a small model of the wing at its extremity; the Wright Brothers and many others used the wind tunnel method, which consisted in placing a model of the wing in a tunnel-like structure through which a draft of air was forced; later a method was devised for carrying a larger model of a wing above a motor vehicle or railroad car.

All of these methods, while giving interesting results, have been found lacking in the accuracy desired in the design of aeroplanes. The information available to a designer should be sufficiently accurate to enable him to predict the ultimate actual performance of a wing on a full-sized aeroplane. In the whirling arm and the wind tunnel methods of test, errors were found to exist due to the small size of the model that could be tested; while in the method of carrying the wing above a vehicle, the interference of the ground and the wind was responsible for the inaccuracy. In short, the reason that no one of these methods proved entirely satisfactory is that the method and equipment used did not even remotely approach the actual conditions of flight.

It was with this in mind that the new method was evolved, in which every detail has been arranged so that the test conditions are as close to the conditions of actual flight as is possible. Under the new method a model wing is constructed to full size and the conditions of test as to speed and altitude of flight can be selected to suit the aeroplane in which the wing is intended to be used, and the qualities of its lift and resistance can be measured directly without an overburdening amount of mathematical calculation. In the preliminary tests of the new method using small models several difficulties were met and overcome and the results obtained are encouraging to the extent that the testing of full-sized wings is in preparation.

The new method consists in suspending the wing to be tested upside down below an aeroplane in flight. It is supported by three steel wires at such a distance that there is no interference from the aeroplane or from the "wash" of its propeller. The wing is inverted so that the lift becomes a downward pull, keeping it away from the aeroplane, and the amount of the pull being equal to the lift when right side up. With the wing so suspended it is possible to measure its lifting force on spring balances directly through the suspending wires, and its resistance from the angle of these wires to the vertical. This, on its face, appears of little difficulty, but as it would be obviously impossible to leave the ground or to land with the model hanging below the aeroplane, it was necessary to take off with the wing hauled up against the plane and to devise a means of raising and lowering the model wing after the plane was in the air. It was in perfecting this apparatus that considerable difficulty was experienced, and twice while in flight the model got beyond control and broke away on one occasion, colliding violently with the tail surface causing considerable damage and threatening the destruction fo the aeroplane in the air and loss of life to the test pilot and engineer. However, remedial changes were made in the apparatus and more careful handling of the wing has reduced this hazard to a minimum.

The method was originated by F. H. Norton, Chief Physicist in charge of aeronautical research at the National Advisory Committee's Laboratory, and the preliminary tests were carried out by him with the assistance of Thomas Carroll, Test Pilot of the Laboratory staff. Twenty flights have been made with the perfected apparatus carrying a model wing six feet long by one foot wide, and the results obtained have checked with remarkable accuracy with the known performance of the full-sized wing of similar proportions upon a full-sized aeroplane.

The testing requires calm air conditions to give the best results and the flight path must be in a straight line. For the purpose of demonstrating the possibilities of the method, however, several flights were made on days when the air conditions were far from ideal and turns made with the wing suspended. It is possible to vary the angle of the model wing to the wind by raising or lowering the rearward suspending wire and the angle is read, with the aid of a telescope, from a small inclinometer or spirit level attached to the model. As the model is carried from twenty to thirty feet below the aeroplane, it is necessary to reel in the suspending wires until the model is close up to the body before a landing may be attempted. It has been found that in gliding onto the field at customary speeds, forces are developed by the model which are nearly capable of tearing it loose. This has been easily corrected by approaching the ground at lower speeds.

While these experiments developed by the National Advisory Committee for Aeronautics are of a preliminary nature they have excited considerable interest among aeronautical men both at home and abroad. The results of the experiments upon the full-sized wings are eagerly anticipated, in the hope that they will solve the problem of providing the aeroplane designer with absolutely accurate performance data, at less cost than for inaccurate data heretofore obtainable.

THE "UNIVERSAL PROPELLER"

By DAVID L. BACON

Langley Memorial Laboratory

THE improvements in aeroplane performance and fuel economy which may be realized by the use of a variable pitch propeller are unquestioned and their more frequent use, particularly on supercharged and multi-engined aircraft, has been delayed principally by the lack of satisfactory designs.

The reversible propeller also has shown decided advantages in decreasing the run of aeroplanes on landing and in the maneuvering of airships.

The helicopter problem which has for centuries been a fertile field for inventors is now attracting more serious attention than ever before and offers attractive possibilities if the obstacle of very large propellers, variable in pitch and of extremely light weight, can be successfully overcome.

A new design which avoids some of the objectionable features of other reversible propellers is therefore of more than passing interest.

At the request of the National Advisory Committee for Aeronautics the "Universal Propeller" was operated and explained by the inventor, Mr. Spencer Heath, for the purpose of demonstrating the following features of its design.

1. Elimination of continuously running gears, collars or bearings in the pitch control mechanism.
2. The use of engine power in place of manual labor in changing the blade angle.
3. The absence of any structural limitation to the range of blade angles available and the possibility of limiting the blade travel between any two predetermined extreme positions.
4. Continuous indication on the instrument board of the blade position.
5. Autnmatic throttling of the engine while the propeller is passing through the position of neutral pitch.

Description of Propeller

The present propeller and operating mechanism represent an experimental development rather than a refined design and as they were built entirely to shop sketches, no scale layout could be obtained and the writer's accompanying sketches are necessarily crude and incomplete.

The two wooden blades are fastened into steel sleeves which in turn are held in a steel hub similar in construction to that used by Hart and others, the centrifugal forces being taken on ball thrusts and torsional and axial forces on plain bearings.

The method of fixing the wooden blades into the steel sleeves is noteworthy. The butt end of each blade is tapered outwardly at a small angle as shown in Fig. 1, and the surrounding collar is split so that it may be first sprung over the butt and then compressed upon the taper.

Pitch Changing Mechanism

The pitch changing mechanism is operated through the application of a braking force to either one of a pair of small brake drums surrounding the engine crankshaft and normally rotating with it. The elementary principle is shown in Fig. 2, which represents a brake drum connected through a gear train to the individual blades of the propeller. It is apparent that if the drum is allowed to revolve at crankshaft speed, all the gears will be stationary relative to the propeller and that the pitch angle will remain constant. If, on the contrary, the brake drum is held stationary the gear train will he set into action and the pitch angle of the blades will undergo a continuous change until the brake drum is released.

In order to change the blade angle in the inverse direction a second brake drum may be used, connecting to the worm shaft through an idler which serves to reverse the direction of rotation of the worm shaft. It should be noted that during normal flying none of these gears are operative and that the blades are locked in position by the non-reversible features of the worm and the friction of the connected parts.

The actual construction of the pitch changing mechanism used by Mr. Heath is shown in Fig. 3. It will be seen that the mechanism has been somewhat complicated by the necessity of obtaining a large speed reduction ratio between the brake drums and the propeller blades. The brakes are applied through leather faced aluminum shoes operated from the pilot's seat by a light push and pull knob attaching to a brake lever mounted on the drum housing. A small hand crank is provided

Fig. 1. Split steel sleeve compressed about butt end of propeller blade.

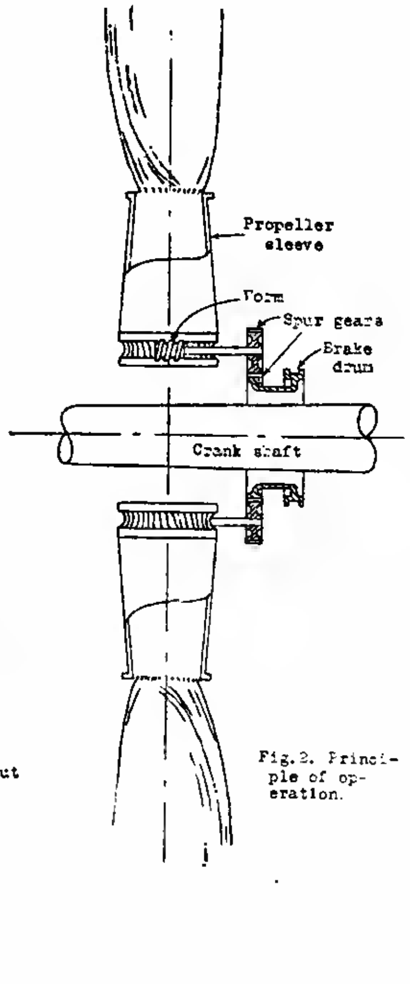

Fig. 2. Principle of operation.

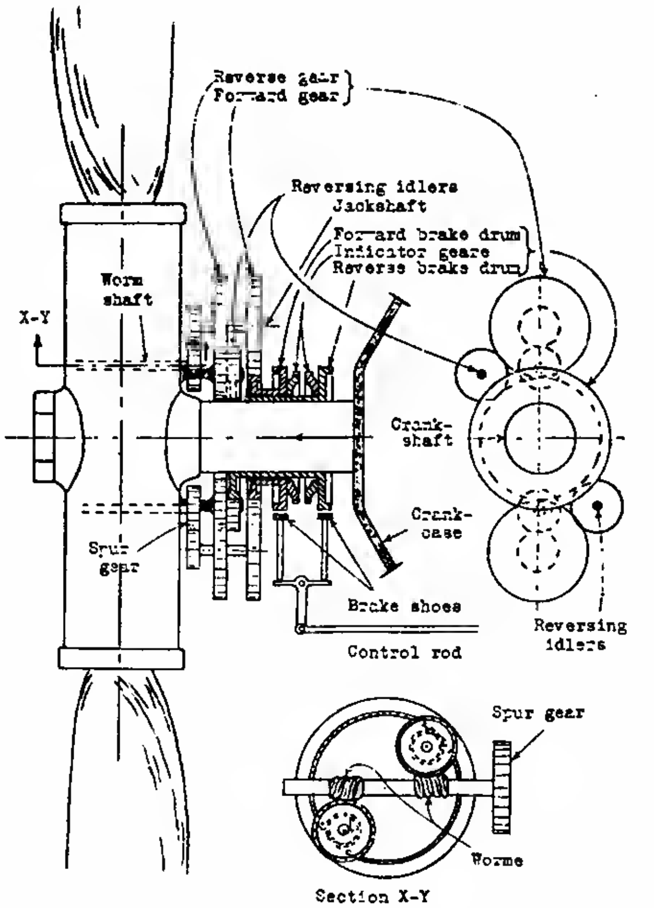

Fig. 3. Pitch changing gear train.

Digitized by Google

by which the pitch can be changed while the engine is not running.

Blade Position Indicator

The angular setting of the propeller blades at any instant is a function of the relative motion which has taken place between the two brake drums. The indicating mechanism is therefore operated by gearing from the two brake drums which conveys differential motion to the indicating pointer and the throttling and pitch limiting cams. As long as the two brake drums revolve both at crankshaft speed the indicating hand remains stationary while if either of them is retarded an angular motion is shown on the indicator equal to that experience by the blades themselves.

Automatic Throttle Control

The mechanical throttle is provided with springs in both directions so that the pilot can at any time by applying a force on the throttle greater than the initial tension in the springs substitute manual for automatic control.

Pitch Limiting Mechanism

In the pitch limiting mechanism the control knob normally connects to the brake levers direct, a push increasing and a pull decreasing the pitch. If the control button is held in either operating position until the limiting position of the propeller blade is reached the cam trips a latch plate and renders the control inoperative in that direction while leaving it ready for use in reversing the direction of propeller blade motion.

Demonstration Under Power

To show the action under power the propeller and related mechanism were installed on a 150 HP Hispano-Suiza engine mounted with gasoline tank, observers' seats, etc., on a lumber trailer weighing about two tons which was free to roll on the ground between two chocks a few feet apart. The engine and propeller were operated both by Mr. Heath and the writer and put through their entire range of performance, which included disconnecting the pitch limiting mechanism so that the blade angles were controlled throughout a complete revolution of 360 degrees, both forward and reverse.

With the engine turning at about 1,000 r.p.m., the angular change from full speed ahead to full speed astern was accomplished in about five seconds.

Conclusions

The present mechanism, although but a crude embodiment of the inventor's principle, fulfills his claims at listed at the beginning of this report, and might easily be redesigned into a practical flying accessory.

It is obvious that some of its advantages are gained at the expense of additional complication and the question immediately arises whether they are worth it. In the opinion of the writer the novel features of this propeller are of sufficient value to warrant its redesign in a compact and lighter unit for prolonged service tests on either aeroplanes or airships. Any pitch changing mechanism for use on a helicopter must necessarily be designed as an integral part of the structure, and it remains to be seen whether designers will care to use Mr. Heath's patented ideas or will prefer to undertake the additional and by no means simple task of inventing and perfecting some mechanism of their own.

PUBLICITY BY AEROPLANE

By ANDRE CARLIER*

of the Compagnie Aérienne Francaise

No one can now foresee the new applications which circumstances may any day bring forth for the utilization of the aeroplane aside from commercial transportation. We must try to discover them, as the only means of assisting aviation to live. One of the most important branches of aerial activity is publicity by aeroplane. It may assume various forms and has already been employed with marked success.

In the first place, aerial photography will henceforth constitute one of the resources of every publicity agent for any large company. Why? Because the most natural desire of a chief of industry or a wise manager is to show the world that his factories exist, that they are in perfect order and that they cover a respectable area. Twenty years ago there were artists who specialized in this kind of illustration, with the aid of photography. With great difficulty, by climbing to the top of a chimney, they obtained a more or less successful bird's eye view. Everybody has seen on catalogs these pretty pictures with diminutive people on the ground and delivery wagons larger than the buildings themselves. Though some were well done, most of these pictures were infantile.

We know a celebrated factory on the Marne, the manager of which did not hesitate, at the time of the Chicago exposition, to build a wooden tower, 60 meters (nearly 200 feet) high, in order to obtain a single panoramic photograph. At that time there were no aeroplanes.

Now all the large manufacturing plants have in their files superb aerial photographs taken at an altitude of 500 to 800 meters and showing their establishments from all sides.

These views serve alike for illustrations in catalogs and for letter heads. They can be reduced for making post cards or enlarged for placing in waiting rooms or offices, or for decorating the stands at the next fair or exposition.

These panoramic photographs show in a striking manner the designs of our castles and parks, and will constitute the best advertisements for our architects.

. Aerial photographs will serve to advertise estates and building lots and each one can select his lot without visiting it, because the real estate company will have in its office the field itself, with its trees, its meadows, its brooks and rivers and all shown in relation to one another much better than on the estate itself.

They will be of service to engineers in planning factory extensions.

This will be the best way to exhibit in other countries the beauty spots of our own country, either by the use of lantern slides or by a collection of handsome enlargements.

Publicity by aerial photography will not stop here. Magazines and newspapers will resort to it more and more. After the catastrophe at the Baden Aniline Works, "L'Illustration" immediately requested the "Compagnie Aérienne Francaise" to send one of its operators by aeroplane to take aerial photographs of the ruins. In 48 hours the aeroplane departed, the photographs were taken and the negatives delivered to the journal which published, the following Saturday, a large double-page picture of the catastrophe.

Aeroplanes are coming daily into more extensive use, not only for taking aerial photographs but also for the rapid transportation of pictures taken by ground photographers. The "Daily Mail" employs no other means for transporting its photograms and kinetograms.

Another method of advertising by aeroplane is to drop circulars, either directly or with the aid of parachutes. Experience has demonstrated that all papers falling from the sky are immediately picked up and religiously carried away by the person who is able to get possession of them. In order to add interest to this method of advertising, it is evidently necessary to drop a large number of circulars, for a few thousand do not make much show. On the contrary, when a million or two circulars of all colors are dropped on a city or any large gathering, inside of half an hour, the effect produced is enormous. If, in order to increase this effect, a thousand parachutes, weighted with any kind of advertisement, are dropped, the crowd simply goes wild to get hold of them.

This method of advertising is of interest not only to manufacturers of products of wide consumption, like food and pharmaceutic preparations, etc., but also to large banks for arousing interest in popular loans. The Crédit Lyonnais resorted to this method at the time of the last government loan. Our aeroplanes, in fact, can come into direct contact with the thrifty man in his provincial city, in his village, and even, if necessary, in the fields and at his plough.

All these methods of publicity can be made still more effective by assembling, in advance, several thousand people at the same place, which is the object of the "Reunion Aérienne." These "aerial gatherings" may last one day or several, or even a week, like the one recently held at Dinard by the D. R. P. (League for the defense and rehabilitation of the country,) which was a great success.

An excellent advertisement for an exposition or a fair is the organization of an aerial taxi service between the city and the grounds. The Germans showed a perfect understanding of this fact, when they organized during the last Leipzig fair, an aerial service between that city, Berlin and the other large cities of Germany.

The promoters of the Lyons fair are considering a similar plan for next year.

From what we have seen, we may conclude that the employment of the aeroplane for advertising purposes is still in its infancy and that, by constant collaboration with other means of publicity, such as the daily papers, bill-boards, etc., results may be obtained, the importance of which it is still difficult to estimate.

HYDROSTATIC TEST OF AN AIRSHIP MODEL

An airship model made by the Goodyear Rubber Company, was filled with water and suspended from a beam and the deformations of the envelope studied under the following conditions:

(a) Both ballonets empty;
(b) Forward ballonet filled with air;
(c) Rear ballonet filled with air;
(d) Both ballonets filled with air.

Photographs were taken to record the deflections under each of these conditions, and a study was made to determine the minimum head of water necessary to maintain the longitudinal axis of the envelope under these conditions. Additional photographs were taken of the model filled with air and after filling with water before any adjustment of the suspension was made. The form of the cross section when filled with water was obtained by bending a heavy piece of fuse wire to conform with the surface and then by laying the wire on paper and tracing the shape. The effect of filling with water on the length of the model was also noted.

Apparatus Used.—As may be seen, from the following photographs, the model was suspended from a framework in front of a vertical screen of cross section paper having lines one inch apart. The tension in the cords was adjusted by screwing up the nuts on the ⅛-inch brass rods which ran through the beam, as shown in the photographs. The lower ends of these rods were bent to form hooks into which the cords were tied.

Conditions of Test.—Six cords on the end, both forward and rear were run to a single ring and fastened. In this test they were run through the ring in order to provide for adjustment of each cord. The rings were held in place by a wire, which may be seen in the photograph, and which was fastened to the Vee, at the end of the third cord from the end on each side. When filled with water an upward force was exerted near the stern at the position occupied by the rudders and fins on the airship. The weight of the fins and rudders on the full-size airship is 480 pounds. The forces acting on the model are $\frac{1}{30.18}$ times those on the full-size airship; hence this upward force was made $\frac{480}{30.18}$, or 15.9 pounds. This force was measured by supporting a stick at its middle on a knife edge and hanging a weight of 15.9 pounds on one end; while from the other end, as is shown in the photographs, the stern of the model was suspended. It will be noted that the moment exerted by this force, tending to tip the stern up, is $\frac{1}{30.18^2}$ times the moment of the rudders and fins on the full-size airship, and as the cords were adjusted to a length equal to approximately $\frac{1}{30.18}$ times that of the full-size airship, the moment of the weight of the model about the ends of the cords near the beam is $\frac{1}{30.18^2}$ times the moment in the full-size airship; hence the moment exerted by 15.9 pounds is correct in this report. It may also be shown that the stress in the fabric caused by this moment is the same as in the full-size airship. The flat sticks under the band were simply to distribute the force of the band in a way similar to that in which the force of the fins and rudders is distributed in the full-size airship, and to prevent the band making a deep indentation in the model.

The entire apparatus was mounted on platform scales in order to determine the change in weight under the various conditions.

The pressures used were measured by manometer tubes, as shown in the photographs, and were as follows:

Pressure of air (air filled) ....19½ in. water
" " water (water filled) .... ¼ " " (approx.)
" " air in forward ballonet.....20 " "
" " air in rear ballonet.........20 " "
" " air in both ballonets
(used together)...........15 " "

The pressure of the air when air-filled was made 19½ inches because about this pressure was necessary to straighten out the wrinkles and give the model a fairly smooth appearance. It was assumed that the same pressure would hold the ballonets in shape, and hence it was used. Due to a leak in the connections when both ballonets were filled the pressure had dropped to 15 inches when the picture was taken. This was considerably in excess of the water pressure on the outside of the ballonets, hence they must have been completely filled in all cases. One-quarter of an inch of water was used as this was the smallest amount that would indicate with certainty that the model was filled. A slight change in the air pressure occured constantly, due to the cooling of the air after compression and also as a result of leaks, caused the water level to change slightly, requiring that a slight head be used to make sure that the head did not become less than zero. Considering that the fabric in the model might take the form of that in the full-size airship, a quarter-inch head, equal to a probable increase of ¼" in the vertical distance from top to bottom of the envelope, was taken as zero head.

Correction for Readings on Cross-Section Paper.—The lens of the camera was kept at a constant distance of 200 inches from the screen, measured in the path of the light. As the distance from the axis of the model to either screen was 9 inches, the actual dimensions of the model may be determined

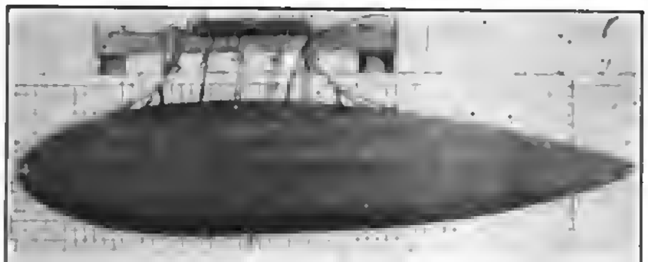

Fig. 3. Filled with air.

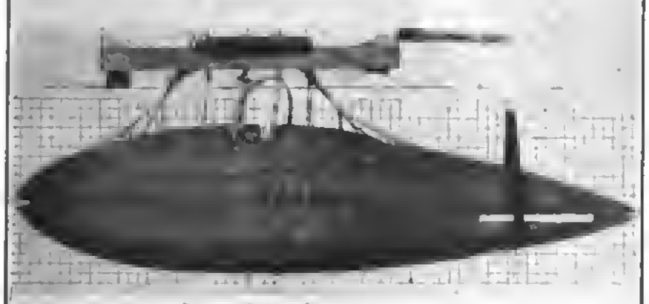

Fig. 4. Filled with water (not adjusted).

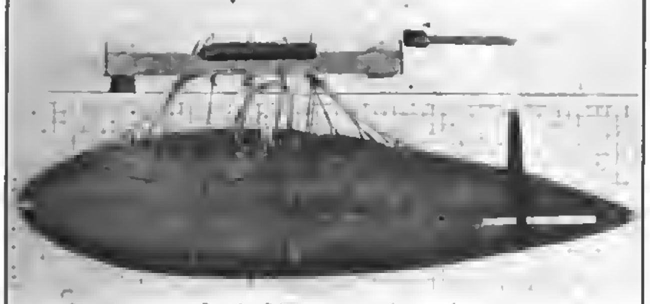

Fig. 5. Filled with water (adjusted).

for any point on it by reading the dimension on the cross-section paper and reducing it by the ratio $\frac{200-9}{200} = .955$. If a greater accuracy is desired, a correction for the inaccuracy of the paper should be made; the actual width being 1911 inches instead of 20 inches. The correction lengthwise will be by the same ratio, of course.

Discussion of Photographs

Filled With Air.—Fig. 3 shows the model filled with air and was the first one taken. The model had stood for several days filled with water, and it presents a much smoother appearance than when first filled with air before standing filled with water. It was found necessary in order to bring the model to a horizontal position to support nearly the entire weight by the cords furthest to the right to those which appear vertical in the side view. The other cords were drawn up as far as possible without causing any appreciable tension.

Filled With Water (not adjusted).—Fig. 4 shows the model filled with water, no adjustment of the cords having been made after taking the photograph, Fig. 3. It will be noted that the stern had sagged more than the prow and there was an off-set in the axis under the rear end of the belly band. The vertical cords toward the rear were too tight, causing a narrow section to show from a top view. It is not only the cords which took the weight when air-filled, however, that were too tight, as those just ahead of them appear equally stressed. The foremost of the cords passing through the rear ring caused an indentation and for this reason they were removed from the ring before the next picture was taken. The indentations around the ballonet valves were due to the fact that the cords attaching the ballonets to the envelope were too short. The wavy appearance of the sides was due to the seam and most of these waves did not extend much beyond the seam. The waves in the belly band took the form shown accidently, and did not indicate that the cords would cause a similar form on the full-size airship.

Filled With Water (adjusted).—The following adjustments were made before taking photograph, Fig. 5. Numbering from the stern No. 3 cords were taken out of ring and adjusted, which caused the position of the ring to change. Nos 1 and 2 were taken up about 1 inch; No. 5 was let out about ¼ inch. The rear cords were not tightened more because of the wrinkle which began to appear just under their upper ends and because tightening them threw the cords, which appeared in a vertical plane in the plan, more and more out of the vertical. The axis of the model was, however, straightened considerably in this way, as may be noted.

Forward Ballonet Filled With Air.—The principal effect of filling the forward ballonet with air, as shown in photograph, Fig. 6, was to tip the forward end up and to broaden it, the broadening being chiefly due to the increased tension in the cords holding the ballonet. The model at the same time moved forward as is shown by the increased inclination of the cords. Due to some peculiarity in the lighting, the liquid in the tube did not register clearly, but the pressure was about 20 inches of water. The tension in the rear vertical cords was increased, as is shown by the tendency to wrinkle on the sides under them.

Rear Ballonet Filled With Air.—Filling the rear ballonet with air, as shown in photograph, Fig. 7, had the same effect as that in photograph, Fig. 6, except that it was at the other end while the dent under the beam toward the rear end which disappeared in photograph, Fig. 6, reappeared here. The cords in the middle section swung to a vertical plane, those farthest forward taking the greater tension.

Both Ballonets Filled With Air.—In this condition, shown in photograph, Fig. 8, the axis was in nearly the same position as with both ballonets empty, except that the stern was higher by about 1½ inches. The cross-section at each end when the ballonet at that end was filled was of this form.

It was noted from a plan view that the filling of either of the ballonets with air distorted the stream line form considerably.

Force Exerted by Ballonets is of Proper Magnitude.—That the buoyancy of the air in the ballonets is of the proper magnitude, i. e., $\frac{1}{30.18}$ times the negatve buoyancy of the ballonets full-size airship, is evident from the following reasoning. A ballonet from the full-size airship immersed in water would have 909 times the buoyancy in the opposite direction, but the ballonet in the model has $\frac{1}{909 \times 30.18}$ times the volume of the

In the War Department's June Sales

Every sale holds real investment VALUE for somebody. To take advantage of the opportunities offered by these sales there are several well defined steps you should follow. First—Write for catalogs of sales that interest you. Second—Make a study of the wide range of commodities listed. Select those items on which you will want to bid. Third—Send your own representative, or instruct someone to act for you.

You will see in the list of War Department Sales the location and dates of sales of the various materials. This outline will assist you in planning to take advantage of those sales most important to you.

For further information regarding all War Department Surplus Property Sales, write:

MAJOR J. L. FRINK

Chief, Sales Promotion Section, Office of Director of Sales

2515 MUNITIONS BUILDING, WASHINGTON, D. C.

Future sales in project include:

AIR SERVICE MATERIAL:

Curtiss Elmwood Depot, Buffalo, N. Y.; Long Island Engine Plant, N. Y.; Americus, Ga.; Richmond, Va.; Morrison, Va.; Montgomery Repair Plant, Ala.; Chapman Field, Fla.; Carlstrom Field, Fla.; Dorr Field, Fla.; Park Field, Tenn.; Selfridge Field, Mich.; Fairfield, Ohio; Love Field, Texas; Houston, Texas.

ORDNANCE MATERIAL:

Amatol Ordance Reserve Depot, N. J.; Amatol Village, N. J.; Erie Howitzer Plant, Erie, Pa.; Picatinny Arsenal, N. J.; Aberdeen Proving Grounds, Maryland.

QUARTERMASTER SUPPLIES:

El Paso, Texas.

(*Continued from page* 158)
times the volume of the full-size airship ballonet; hence the force which it exerts is $909 \times \frac{1}{909 \times 30.18} = \frac{1}{30.18}$ times the force exerted by the full-size airship ballonet; hence the ratio is the same as for the other forces.

Relation of Stresses in Model to Those in Full-Size Airship.—The reason for making the model $\frac{1}{30.18}$ scale was that under this condition the stress in the fabric when filled with water is equal to that in the full-size airship when filled with hydrogen. A proof of this is given in the note following the data. The weights of the hulls, however, act in opposite directions in the two cases. In the full-size airship it causes no tension on the cords and increases the tension in the fabric on the top. In the model the weight is taken by cords and the stress in the fabric just outside of the belly band is increased. This difference may be eliminated by placing a rubber tube filled with air inside the model. It was impossible to place this tube inside this model, however, without making an aperture in the envelope, which was not thought desirable nor necessary as the weight of the hull was very small compared with the weight of the water, whereas in the full-size airship it is much greater compared with the buoyancy.

Action When Partly Filled.—In order to obtain additional data to aid in deciding as to the pressure to be recommended, additional tests were made as follows: Water was drawn from the water-filled model with ballonets empty until the tail collapsed, due to the rudder and fin weight. This occured when the level of water was about two inches below the inside edge of the belly band. To bring it to this level about 1/3 of the total weight of the water was drawn off. On the following day this part of the experiment was repeated at which time the level was brought 3½ inches below the inside edge of the belly band before a collapse occured. This difference in results is explained by the fact that when the model is only partly filled it is in an unstable condition. If for any reason the water starts to run toward one end, that end becoming heavy sinks while the other rises, and the water rushes to the lower end. The first day that this part of the experiment was made, when a level of two inches below the inner edge of the belly band was reached, the water began to run forward and a collapse occured. The second day it started to run in the opposite direction, a crease developing under the rear filling valve which became 1½ inches deep before the water began to run the other way and a collapse occured.

Action of Rudder and Elevator Forces.—It was calculated that at 45 miles per hour and with the rudder at 30°, the force on the rudders for a model of this size would be about ¾ of a pound, and the force on the elevators would be approximately the same for this condition. However, as the other forces are 30.18 times those, correct to scale, for a model of this size, the rudder and elevator forces must be increased in the same ratio; hence a weight of 22½ pounds was used to represent the total pressure on the rudders, and the same weight was used to represent the total pressure on the elevators. The effect of hanging this weight on when with a head of ¼-inch (ballonets empty) was to deflect the stern about 8½ inches. When exerted sidewise the deflection was about one foot. Under a head of 10 inches the deflection was about 3½ inches down and five inches sidewise.

Action With Rudder and Fin Weights Removed.—A head of 10 inches was then put on the model, and the rudder and fin weights removed. The axis was not bent noticeably due to this removal, although the inclination was of course changed. The head was then decreased and the axis gradually bent until at one-inch head it had bent so that the stern was about five inches lower than with the 10-inch head, and it was also bent to the left about six inches and there was a fold in the fabric on the left side and bottom about 1¼ inches deep under the rear filling valve.

Change in Volume With Pressure.—Under the 10-inch head the weight was 483 pounds, an increase of about 4 per cent in net weight over that for ¼-inch head. However, there would be a much greater percentage increase in buoyancy in the full-size airship due to this increase in head.

Cross sections of the water-filled model with ¼-inch head are shown on Fig. 1. As previously stated these were obtained by bending a heavy fuse wire around the model. The tracing thus obtained was then reduced by the pantograph to the size shown in the figure. As noted above, the form when the ballonets were filled was with a valley on the under side. As this was due chiefly to the ballonet cords being short and would not occur to the same degree in the full-size airship, no reproduction of the cross section, when the ballonets were filled, was made.

Conclusion.—From the above it appears that any pressure sufficient to keep the airship full may be used. No data was obtained which could be used to determine to what extent the wind would affect the deformation. But it appears that a pressure of one inch of water would provide a suitable factor of safety, and therefore this is the pressure recommended. Due to the negative buoyancy of the ballonets, a pressure of about 0.4 of an inch of water in excess of the pressure used on the hydrogen is necessary to equalize the pressure inside and out at the top of the ballonet. This difference between air and hydrogen pressures should be increased to probably at least ¾ of an inch to compensate for the weight of the ballonet and for the tension on the cords.

DIMENSIONS OF MODEL

	Condition	Dimensions in Inches
Length	Air filled	61.4
	Water filled, not adjusted	61.1
	Water filled, adjusted	61.0
	From specifications: $\frac{1}{30.18} \times 160 \times 12$	63.6
Maximum diameter	Air filled, actual	13.4
	From specifications: $\frac{1}{30.18} \times 31.5 \times 12$	12.5

WEIGHTS OF MODEL

"	10" head	None	483
"	——	"	422 *
"	——	"	403 **

Short Proof That Stress in Fabric in Model Equals That in Full-Size Airship.—This proof is based on the fact that in a model made exactly to scale throughout, the stress per unit area, in any number, is the same as in a full-sized airship, if the pressure per unit area of the liquid remains unchanged at all points. This is the case, however, that the head of the water is rightly chosen, both pressures are the same function of the height. This necessitates in addition that the liquid used in the model have a greater buoyancy (positive or negative) than that used in the full-size airship, and if the thickness of the fabric in the model be reduced by the ratio $\frac{1}{n}$, which is the scale of the model, the buoyancy of the liquid used must be n times that of the hydrogen, but if it be not reduced, the cross sectional area of the fabric in any plane is n times as great as it should be to cause the desired stress with a fluid having a buoyancy n times that of hydrogen. Hence, in order to cause the stress in the fabric of the model to equal that in the full-size airship, it is necessary to make the buoyancy of the liquid n times as great as it would be if the thickness of the fabric were to scale. The ratio of the buoyancy of the liquid to be used, to the buoyancy of hydrogen, is therefore n^2. The ratio of the buoyancies of water and hydrogen is 909. The scale to be used is then $\frac{1}{\sqrt{909}} = \frac{1}{30.18}$. The negative sign is not introduced in connection with the buoyancy of water

* At point of collapse, first trial; level of water 2 inches below inside edge of belly band.

** At point of collapse, second trial; level of water 3½ inches below inside edge of belly band.

Weight of water which model should hold, calculated from displacement given in specifications (77,000 cu. ft.) $= \frac{77,000 \times 62.4}{30.18^3} = 175$ pounds.

Weight of water actually held by model at 10-inch head = 483 lbs. — 311 lbs. = 172 lbs.

The Beautiful Sky Below

The call of cloud-blown space may claim you,
  Where sifting sunbeams set the world aglow.
The pall of the lonely void may awe you,
  As drifting shadows cross the earth below.

The thrill of it all may wing you beyond
  Where ages have bade man call a halt.
Its beauties may enhance your gift of gab,
  Where lobbies hear you fly it to a fault.

But;
You and I, and the rest of the guild,
  When the crate falls into a spin,
Think less of the beautiful sky above
  Than what's left of the sky we're spinning in.

So, the azure dome and its infinite span
  Are yours (things O. K.) for mind's romance.
Yet, you'll glory more in the last few feet,
  When you've just won out on a long shot chance.

A. A. C.

Why Pick on Aeroplanes?

Every month there are thousands killed, by automobiles,
These days it happens so often, that we take it like our meals.
Railroads mangle & kill, their victims by the score,
'Tis such a common occurrence, we don't mind it anymore.
Constantly by the street cars, there are scores killed,
They jump the track & smack one black, keeping hospitals filled.
The news "paupers" bought & supported, by these two industries,
Say scarce a word of all these things, for fear of getting a freeze.
A short time ago a foreign balloon, not an AEROPLANE,
Blew up & the papers of the world, chucked it in every brain.
On a basis of passengers carried, & actual miles flown,
'Tween autos & planes for-safety, the Planes take the bone.
Statistics have been handed, to the shyster newspapers,
And they refused to publish them, specialy the auto's capers.
But let an accident happen, to an Aeroplane,
The newspapers of the world, shout it in loud refrain.
Because 'tis such a scarce thing, & also such good news,
To bring to them from the public, all their coppers loose.
From railroads & auto manufacturers, it also brings fat dues,
Just like the old proverbial, the golden egg'ed goose.

H. T. Haller.

Clouds

By Contact

As I go thru the sapphire ways of the air
And over the mosaic maps below,
My thoughts often turn to the clouds floating by
And I wonder at them as they come and go.

Their fleecy shapes of silver white
I see on days so fair.
These faithful wanderers of the sky
Are my companions of the air.

And along thru the endless trails of space.
The snowy shapes go floating by
Slowly, peacefully, undisturbed
Save for my plane that roars on high.

Then, oft I have seen them as peaceful sheep
In the pathless meadows of the sky,
And have lightly touched their curving shapes,
In the course of my flights which have carried me high.

And before me I've seen them in one sullen mass
As if to bar me and my powerful flight!
Then I immerse my ship in their misty shapes
And find myself lost in a sea of white.

Between, above and below the wings
Come ghostly opals in lazy flight
Blown by the four winds of the sky
On thru the day and on thru the night.

Will You Remember?

1

Heart of gold, before the sun is high
  And a plane travels through the golden sky
While the sun from east, with golden gleam
  Goldens your house, mountain and stream.
From up high small appear human dens,
  And morning peace thralls the souls of men—
Heart of gold! do you remember then?"

2

And when you see a plane high in eastward flight,
  And thunderstorms darken day into night,
When lightning forces its way to ground
  And everything toward shelter is bound,
When a bolt will light up cattle and pen
  And ghostly fears will shroud the souls of men—
Heart of gold! will you remember then?

3

When sometimes you'll see a drowsy sky
  Remember the flight we had, you and I?
We were flying over those mountains and trees
  It must still live in your memories—
The cattle were grazing behind the pen
  And peace went into the souls of men—
Heart of gold! will you remember then?

B. K. R.

The Call

Do you ever have a longing to get in the air again
  And to face the same old dangers like a reg'lar flying man?
Do you ever have a yearning just to try your luck once more
  Rather facing thunder and lightning than to be inside that door?
Do you ever sort of hanker for a rough and ready trip,
  Just to prove you're still a living and you haven't lost your grip?
Do you ever get a feeling being cramped and useless here,
  Making figgers while you shine your pants upon an office chair?
Do you ever pass a paintshop, and so get the smell of dope?
  Know the time that you were trying getting it off your hands with soap?
Do you ever pass a field; getting the castor oil odor,
  Don't you wish to have the stick in hand and a roaring motor?
Don't you ever wish to be back just for one more flight,
  Just once more in the game again and a real aerial sight,
If not for any particular reasons, give your friends the laugh
  And so show the roaring element that you still can stand the gaff.
If you don't, then heaven help you and you sure are dying then,
  You might once have been a pilot but never a flying man.

B. K. R.

Johnny: "The camel can go eight days without water."
Freddy: "So could I if ma would let me."

Winner at a Glance

Algy: That vulgah puhson mistook me for a racing man.
Sally: How was that?
Algy: He said I won the Brown Derby.—*Stanford Chaparral.*

"Cheese, sir?" inquired the waiter.

"Certainly," replied Besse. "Catch me a Limberger!"

The waiter made a grab at the sideboard and seized one in the nick of time.

"Now catch me a Gorgonzola!" said Besse.

Grappling with it violently, the waiter brought it over.

"Now," said Besse, "let 'em race across the table to me and I'll take the winner."

FOREIGN NEWS

Laws and Regulations Governing Aerial Navigation in Italy

The Division of Civil Activities of the Office of the Chief of Air Service from time to time will publish bulletins on the laws, regulations and provisions governing aerial navigation in Italy. The object of this publication is to furnish to all persons and companies interested in aerial navigation the laws and regulations governing this matter that are in force at the present time.

The following is a translation of Circular 0005322, establishing the rules for the employment of the term "Air Route" for telegrams and phonograms:

For the purpose of insuring continuous communication between air ports, in the transmission of news relating to the movements of aircraft, in compliance with the agreement made between the Ministry of War and the Ministry of Post and Telegraphs, the latter, on special behalf of air navigation, has allowed the form "Air Route"—already in use for telephone communications—to be extended also to State telegrams which, therefore, will enjoy the absolute precedence over all other telegraphic correspondence.

1. The term "Air Route" shall be used for communicating only the departure or arrival of air-craft, convey news to the interested Headquarters concerning important incidents to air-craft during their journey (landing outside their stations), to communicate important meteorological information in connection with air navigation, calls for assistance, etc.

2. All notices regarding the movements of air-craft in navigation shall be transmitted by telephone which shall be considered as the most preferred, quickest, and normal means of communication. Therefore, a telegram bearing the wording "Air Route" shall not be transmitted except when it has not been possible to convey the communication by telephone.

3. The permission to use the form "Air Route" in telegraph and telephone communications is granted only to the regular commanders of air posts, fields, repair depots, naval air stations and, during their absence, only to those persons designated by them.

4. The permission referred to in the above paragraph is extended to the Commanding Officers of the Royal Carabineers when they must convey information regarding the landing of air-craft outside their field. In such cases the form "Air Route" shall be used only for the transmission of telegrams to the air port interested in the case, as the communications to other offices must be transmitted by the ordinary means.

5. The same permission is granted to corporations or private parties engaged in aerial navigation. Such concession is, however, subject to the following conditions:

a. To possess the Ministerial Decree conferring the right to carry on aerial navigation services;

b. To carry out such right on private fields, their own property, and when duly authorized, and when there is no governmental representative, for in this case the permission is granted only to the latter;

c. To have requested (on stamped paper of Lire 2) and obtained a written authorization from the Ministry of War (Comando Superiore di Aeronautica—Division of Civil Activities) which will, if necessary, notify the Ministry of Posts and Telegraphs and the Telegraph and Telephone Office having jurisdiction over the territory wherein the field is located;

d. To pay from time to time the relative fee for urgent telegrams and phonograms;

e. That in their application they will make a declaration of their readiness to pay the fines mentioned in the Concession for using aircraft, also for every non-compliance with the rules of this circular.

6. The rare and rational use of the form "Air Route" shall be exercised with the utmost scruple, so that the permission granted may not generate into an abuse but remain in the very strict limits allowed.

7. In every air port, field, depot, naval air station, there shall be kept a special register for telephone correspondence or telegraph communications transmitted with the wording "Air Route." Such record book shall contain the progressive number, date, hour of the communication requested, the hour in which the communication has been granted, the address and the text of the telegram or phonogram, references, name of the employees who transmit or receive the communication.

On such record book the text of the telegram or phonogram shall be written and signed by the same parties to whom the concession has been granted.

8. Any abuse whatever in the use of the form "Air Route" will be punished by disciplinary measures and the payment of the expense, if the abuse is committed by a Government Official; by a fine, as referred to in Art. 5, (6) and by the immediate revocation of the concession in case of private corporations.

Italian Aeronautics

In order to establish more rapid communications between Italy and Tripolitania, the Secretary of the Colonies, Hon. Girardini, is endeavoring to organize an aerial mail service from Rome to Tripoli that may eventually be used also for the transportation of passengers. In this way the Superior Command of Aeronautics, which is occupied by every interest in the technical side of the problem, has granted the use of the magnificent dirigible "Esperia" to make its first flight, which will take place in the coming Spring. In the meantime, while they are completing certain works in order to prepare the aeroplane for her flight, her commandant, Maj. Velle, will go to Tripoli personally to make sure of a safe landing.

Meanwhile, the Assistant Secretary of the Colonies, Hon. Verino, has inspected the dirigible "Esperia" at the port of Ciampino. She was built especially for the civil service, and besides carrying a load of mail she may also carry twenty passengers, each with 55 lbs. of baggage, on a long trip, offering them the accommodations of a railway parlor car.

Following the votes expressed by the Aero Club of Naples, through its General Secretary, Mr. Maisto, in the recent meeting of Directive Council of the National Aeronautical Federation in Rome, the International Aeronautical Federation at its last meeting in Paris has decided that the International Race for the "Trophy of the Sea Aviation, Jacques Schneider," will take place in Naples in the latter part of August. The great race will be part of an International Week of Hydro-Aviation, which will embrace also the contests for the "Great Trophy of the Tirrenean Sea" (created by the Superior Command of Aeronautics) over a circuit of 1,260 miles touching several ports of Sicily. Prizes aggregating about 300,000 lire will be awarded to the winners of the various events.

Spanish Appropriations

A Reuter dispatch from Madrid states that the Spanish Minister of War has submitted to the Cabinet a proposal providing for the appropriation of 175,000,000 pesetas for the creation of an aer force of 10 squadrons, consisting each of 18 machines of average size and of six "giant" machines for bombing purposes.

Night Flying Express

The first air express to be fully equipped for night flying left the London Air Station for Paris recently. This machine, the Farman Goliath "Verdun", with accommodations for thirteen passengers, is used regularly now by the Grands Express Aeriens on their daily service between London and Paris. In addition to softly shaded lights in the saloon, red and green electric navigation lights are fixed on the extreme tips of the wings, and a bright rear light is fitted to the tail. Two powerful electric searchlights are placed in the center of the machine below the passenger cabin, and light up the ground over which the aeroplane is flying. The electricity for all this lighting is supplied by two dynamos, which are driven by tiny windmills rotating rapidly in the wind produced by the aeroplane as it rushes through the air. Four powerful magnesium flares are suspended in pairs below each lower wing tip, and the pilot lights these by electricity as he approaches the ground, thus making landing at night an easy operation.

Production in Germany

The work of disarming Germany in the air is ended, according to a correspondent of the London *Daily Mail*. All but 20 of the British, French, Italian, Belgian, and Japanese officers, who have worked under General Masterman on the Inter-Allied Commission of Aeronautical Control, have left Germany. On May 5th the Commission will cease to exist.

Since January, 1920, when General Masterman arrived in Germany, the Commission has destroyed 14,800 airplanes. Of 29,500 motors dealt with, some have been handed over to the Allies, but most of them have been destroyed. Six airships have been handed over to the Allies.

The work of the Commission has been done under great difficulties; never before had the work of disarming a nation been undertaken. When General Masterman demanded a list of places where sheds, works, and airplanes were to be found, the authorities declared that the papers had been lost during the revolution. Only little by little was the necessary information collected.

General Masterman's work is ended, but the control of civil aviation in Germany is to continue. The Council of Ambassadors has not yet published the regulations to be imposed. It is certain that there will be a small permanent Commission with the right of inspection to see that manufacture is carried out within the lines to be prescribed for future German aircraft.

Aerial Touring in North Africa

The first pleasure tour by air across French North Africa, according to Mr. Edward A. Dow, American Consul at Algiers, Algeria, has been undertaken by Mr. Lucien Sharp, of Providence, R. I., an American citizen, now residing temporarily in Paris. Mr. Sharp came by air from Europe to Casablanca, making the journey from that point to Marrakech, Morocco, thence to Oudjs. From the latter point he came directly to Algiers, arriving there January 28th. On January 30th he proceeded to the border of the Sahara Desert at Biskra and Touggoart, and intends continuing his journey by air to Constantine, in Algeria, Tunis, thence to Sicily, Rome, Athens, Constantinople and Western Europe.

The voyage was undertaken in a De Haviland (English) Biplane, and the pilot is an Englishman, Mr. Alan Cobham. There is said to be space for only three persons in all.

Military aviation is being studied in French North Africa. New posts have been established in the interior of Algeria, at Hassi-ba-ba and Laghouat, each about 165 miles from Algiers.

It is proposed in France to endeavor soon to establish aerial tours from Algiers to the desert at Biskra and Touggart, and another cross-country line from Gabes and Tunis, in Tunisia, to Algiers; thence to Oran, Algeria, and Casablanca and Agadir, in Morocco.

A German dirigible "Nordatern" was recently turned over to the French Government, and after repairs have been made, and stations built, it may be placed in operation between Marseilles and Algiers.

Policing Iraq by Aircraft

Sir Percy Cox, High Commissioner of Iraq, made his first inspection by air of part of the country lying along the Euphrates on March 21, when he visited Fahad Beg Ibn Hadhdhal, Sheikh of Amarat, at his headquarters, about 30 miles N.W. of Hit. He was accompanied by his staff and a Royal Air Force guard of honor.

The party, we learn officially, left Baghdad in three Vickers 'Vernon' machines, one of which also carried stores for armored cars, with an air escort of 12 machines.

The Amarat, who are well armed and number 5,000 rifles, range the eastern half of the Hamad as far north as Dair az Zaur. The tribe is regarded as friendly to the British. The effect of the visit and the demonstration of air power by the assembled aircraft, and of machine-gun fire by armored cars, which were also present, is reported to have been very impressive. The flight, which covered about 300 miles out and home, partly following the course of the Baghdad-Cairo air line, was accomplished successfully on the day of the inspection, by the 15 machines engaged.

The Vickers "Vernon" machines which were used for conveying the official party are twin-engined troop-carrying aeroplanes that have been sent recently to Iraq to augment the air units stationed there, and are destined to take an important part in the garrisoning of this vast territory when it comes entirely under Royal Air Force control.

The machine is capable of carrying a load of nearly two tons, and can accommodate 12 persons, with full military equipment, in addition to the pilots, water, and food supplies.

ELEMENTARY AERONAUTICS and MODEL NOTES

Kite Flying

THE behavior of kites is certainly very puzzling to those who do not thoroughly understand the subject. A kite may be made with the greatest degree of perfection, and placed in the hands of one of considerable experience; nevertheless, it may behave very badly, diving suddenly to the ground without any apparent reason. Then, again, this same kite will sometimes steadily mount in the air until it reaches a height difficult to account for.

If the surface of the earth were perfectly smooth, and the wind should always blow in a horizontal direction, kites would not show these eccentric peculiarities, but as a matter of fact, the air seldom moves in a horizontal direction; it is always influenced by the heat of the surface of the earth.

Heated air is continually ascending in some places only to be cooled and to descend in other places. If one is attempting to fly a kite where the air is moving downwards, he will find it an extremely difficult matter, whereas, if he is fortunate enough to strike a current of air which is rising, the kite will mount much higher in the air.

Kites sometimes rise upwards and continue moving into the wind until they pass directly over the spot where they are attached to the earth. It is only on rare occasions, however, that a wind is found to be blowing at a sufficiently sharp upward trend to cause a kite to fly at such an angle. As the center of the upward current is constantly moving, it is certain that very soon it will move away from the point from which the kite is being flown.

An example of the force of rising air currents is seen in the following observations made by a noted scientist during the burning of a large warehouse in New York many years ago. The wind was blowing a gale through all the streets leading in the direction of the fire, although it was quite calm everywhere else. The flames mounted straight in the air to an enormous height, taking with them a large amount of burning wood. At a point fully 500 feet from the fire a piece of partly burned 1-inch board 8 inches wide and 4 feet long, fell through the air. This board had evidently been taken up to a great height by the tremendous uprush of air caused by the hot fire. It is very evident that a kite made of boiler iron could have been successfully flown under these conditions, providing that it could have been brought into the right position.

Model Photographs Wanted

AERIAL AGE wishes to obtain a photograph of the Orenco Fighter model, plans of which were published in the March 14, 1921, issue. Anyone having built a model from these plans, who will send in a clear photograph of it that can be used for publication, will receive in return for it a large sized professional photograph of a well known man-carrying aeroplane.

To the first one sending in a clear photograph of the Curtiss Navy Racer model, described recently, will be sent by return mail a large photograph of the real machine.

Fifteen H. P. Sled Travels 80 Miles an Hour

The motor-propelled ice sled illustrated in the photographs below, is of the latest design by E. J. Andries, 283 East Grand Boulevard, Detroit, Mich. The Andries "Air Sled" was operated for the first time last month on Lake St. Clair. The great interest in this sport is shown by the increasing number of air sleds which have made their appearance on the lake in the past two years.

The body, patterned after the conventional aeroplane fuselage, is made entirely of wood, fibre and aluminum, screwed and bolted to five bulkheads. Steering is accomplished entirely by means of an air rudder, balanced above a short vertical fin and operated by a foot-bar.

A tail skid is provided which comes into play only when excessively rough spots are encountered. The body is fourteen feet in length and weighs 250 pounds. An instrument board carries all motor controls.

Although it is powered only with a 12 to 15 horsepower motor, it is capable of a speed of eighty miles an hour.

Racing Auto Makes High Speed

As far as American aeroplane speed records go, automobiles have the lead on aeroplanes, in one-mile stretches at least. The world's speed record for automobiles has been smashed by Sig Haugdahl, a Norwegian driver, early in April of this year. He negotiated a mile at Daytona Beach, Florida, in 19.97 seconds, slipping 3.1 seconds from the previous record, held by Tommy Milton. Haugdahl's performance gives him a rate of 180.27 miles an hour, which is over 3 miles an hour faster than the Curtiss Navy Racer. It must be remembered, however, that the Navy Racer at times travelled at a much greater speed than this, and that the speed of 177 miles is the average for the entire circuit during the Pulitzer Trophy Race.

Exhibition Model Built by Aerial Age Reader

Several stores in Toledo have displayed the 30-inch exhibition model designed and built by Wilbur J. McKenna, of 115 E. Woodruff Avenue, Toledo, Ohio. Although it was his first attempt at anything of this kind, the model is a very neat piece of work, and attracts many people to view it in the store windows.

The outline does not follow any particular design, but all the conventional parts are arranged as on the average aeroplane. It is equipped with a small 110-volt electric fan motor which drives a propellor 6 inches in diameter. The fuselage is covered with metal over an orange wood framework. Struts are made of copper tubing. Wings are solid wood. The landing gear is provided with rubber-tired disk wheels.

A full set of controls is installed in the cockpit. There are also electric lights and two-speed control lever which regulates the speed of motor.

RADIO DIGEST

Flying Parson's Plane Broadcasts Concert

A radio concert several thousand feet above the earth was broadcasted April 14 as an aeroplane piloted by Lieut. B. W. Maynard, the "flying parson," flew over New York City. The stunt was for the benefit of the fund for a veterans' mountain camp in the Adirondacks, of which Lieut. Maynard is campaign director.

The second flight of the plane was made at 3 o'clock on Sunday, April 16, when Lieut. Maynard preached a sermon from the clouds.

Radio Expert Addresses Aeronautic Executives

One of the largest groups of Aeronautic Executives attended their sixth semi-monthly luncheon at the Café Boulevard, Friday, April 7th.

The speaker, Mr. Jack Binns, Radio Editor of the New York Tribune and the Popular Science Monthly, was introduced to those present by Chairman R. R. Blythe, who in his introduction stated that Mr. Binns, besides being known all over the world as the hero of the sinking of the S. S. Republic, was perhaps one of the best informed men of the use of wireless and radio for aircraft.

Mr. Binns is opening his address pointed out the necessity of equipping all passenger carrying aircraft, operating between two cities, with radio.

"I was asked the other day," he said, "why it was that commercial aviation could not develop overnight, as had radio. My questioner evidently did not know that radio experiments and developments have been going on for the past twenty years and this so-called radio craze is nothing more or less than the result of these years of pioneering effort. Radio on aircraft can serve two purposes. First, it will allow pilots by means of directional instruments to keep on their course, and make a safe landing through fog and heavy weather. Secondly, it will permit communication from the land telephone, via radio, to passengers on aircraft in flight."

Mr. Binns referred to the loss of the independently owned flying boat "Miss Miami" with its toll of five deaths. It was his opinion that these lives could have been saved if a radio set had been on the ship.

In closing, Mr. Binns urged that operators of commercial aircraft particularly the larger companies, should without delay equip each of their planes with radio apparatus. Even if the initial cost was high, one accident would prove the wisdom of such installation.

At the close of the luncheon Mr. Blythe read the text of a resolution calling on the Contest Committee of the Aero Club of America to settle the controversy in regard to the award of the Larsen Trophy, which arose at the Omaha Air Meet last fall. This resolution was signed by all the Aeronautic Executives present, which completed a representation from every reputable aircraft company in the east.

New Amplifier Gives Quality with Volume

Amplification of voice waves, giving the original true quality, increased many thousandfold in volume without a corresponding increase in the distortion caused by reproductions, is the latest progressive step in the development of wireless telephony.

This has just recently been accomplished by the use of the newly marketed two-stage amplifier and loud speaking receiver of the Western Electric Company. Leading New York dealers in radio apparatus witnessed the first demonstration of the device recently.

The machine proved its worth beyond the highest expectations of the engineers.

Harry Goldman, of the Aldan Accessory Company, was among the first to appreciate the possibilities of the perfected device, and immediately asked for the first supply to be given distributors.

Explaining the two-stage amplifier and loud speaker, the details of which he made public for the first time, Mr. Goldman said:

"The new Western Electric two-stage amplifier is a masterpiece. It is a two-stage amplifier, three-tube, with two tubes used in the last stage, the last two tubes controlled by "push-pull" switch. The first bulb is also an amplifying tube.

It succeeds where other amplifiers and loud speakers fail, in that it amplifies ordinary speech and voice currents, keeping their exact tone and quality even when increased 200,000 times, without the usual added distortion.

"To explain it in lay language, if a solo by Galli-Curci is being transmitted, her voice, though increased in volume thousands of times, retains the distinctive characteristics of her particular voice. Whereas ordinarily it would come in as some high soprano, hardly distinguishable from that of any other concert star, the Western Electric amplifier and loud speaker receives it so that it is distinguishably Galli-Curci's voice.

"Here is another way of putting it. When a man speaks in an ordinary conversational tone, his voice is distinctive and natural, yet when he shouts it increases in volume but loses its quality, often cracks. The Western Electric two-stage amplifier, on the other hand, takes the ordinary voice, magnifies it, expands it to what would relatively be a gigantic shout, yet does not 'flatten' it or destroy its tone values.

"Heretofore every effort to do this has resulted in increased distortion.

"The instrument is the same which was used at Madison Square Garden in receiving President Harding's address, and two years ago, when the company's engineers were experimenting with it, Cornell men, speaking into an ordinary telephone receiver, connected with the amplifier placed on the roof of the West street building, spoke to the Aquitania sailing down the bay with the Cornell cross-country team aboard. The Acquitania answered with radio.

"I really believe that it is one of the greatest practical advancements which have been made in the science, as it has already proved its worth and adaptability to ordinary commercial usage."

Easy for Novice to Hear Broadcasts

To the novice, trembling on the verge of entry into the radio world, the aerial is the most formidable of the obstacles to be surmounted before the sweet strains of W J Z enter his ears by way of his own set.

The greatness of the difficulties which he must overcome depends upon many and varied things. If he is an apartment dweller, the temperament of his landlord, the shape and height of the roof, and the nearness of power lines or telephone wires all enter into the matter. If he is a suburhanite, the length of his backyard, the nearness of big trees, and the need for a tower or some other support, preferably higher than the house end of his antenna, all enter into the matter.

The radio amateur who desires only to listen to the broadcasts sent out by Newark, Pittsburgh, Springfield or Medford Hillside, need not lose too much sleep and hair over his problem, for all he needs is a single stand of wire, preferably between 175 and 200 feet long, of copper, phosphor-bronze, or aluminum, slung at from thirty to fifty feet above the earth.

A somewhat more elaborate antenna is needed by the novice who hopes some time to go into the sending end of the game, but these are not so terrifically difficult as they may seem after listening to the chatter of expert amateurs.

Three types of antenna, the inverted L, the T and the umbrella, which are sufficiently efficient for the work contemplated.

The first of these, much used on ships, is called the inverted L, because the lead-in from the four strands composing it is from one end, giving the appearance of an L with its toe pointing earthward. If you desire to receive one station particularly well—Newark, for example—the aerial should point in that direction, with the lead-in to the apparatus indoors from the nearest end of the station. This type is particularly effective in receiving long wave stations. The length of the aerial should not exceed 100 feet, as in sending a longer aerial would give a natural wave length above the 200 meters at present permitted to amateurs.

The second type, the T, is much like the inverted L, for it consists of four wires suspended in the same plane. The lead-in to the set in the case of the T, however, is directly in the center of the span. The amateur must take care to get the precise center if he hopes to secure the maximum efficiency of his aerial.

The T type should not be longer than 135 feet, and neither of these aerials, if used for transmitting, should be higher than thirty-five feet. Otherwise the natural wave length will exceed the present 200 meters permitted. In the use of this aerial the amateur will discover that the waves come in strongest from stations which are in line with the length of the antenna.

The third type of aerial, the umbrella, is more or less of a makeshift, designed for use where the spanning space is not sufficient for either the inverted L or T aerial. This type receives or transmits

Digitized by Google

waves equally well in all directions, but is not a very good radiator in any direction. It consists of a pole or mast, from which four wires stretch downward and outward. The lead in this case is from the upper end of these wires, which are, of course, carefully insulated from both the pole and the stakes at the foot, holding the antenna wires.

There is nothing particularly mysterious about the aerial or its insulation. The object of the aerial is to intercept feeble radio waves. These waves induce in it a current of feeble voltage, but of high frequency oscillation. Naturally this wire should be a good conductor and should be insulated from its supports, so that the whole energy of the current may be led to the receiving apparatus which is to translate it into sound, slight or great, according to the apparatus. Greater care in insulation should be taken if the aerial is to be used for transmission.

The insulators may be purchased, if other amateurs have not already cleaned out the nearby stores, or ordinary electric light wire porcelain cleats may be used. The lead-in must also be carefully insulated and should be kept clear of all obstructions.

The lead-in should be brought down to a knife blade switch which may direct the current either to the set or through an outdoor connection to the ground. This switch should be thrown to send the current on the latter path when not in use or during thunderstorms. The radio instruments inside the house should be connected permanently to a ground, preferably to a water pipe, by ground clamps. A radiator or a gas pipe may also be used as a ground. —N. Y. Herald.

The Brooklyn Show

Several interesting contests that will appeal strongly to amateur fans are being planned for the first annual radio and electrical exhibition of the Electrical Contractors Association of Brooklyn and Queens to be held in the Brooklyn Ice Palace, starting May 6 and lasting two weeks.

One will be a contest for the Brooklyn Council of the Boy Scouts of America. The Boy Scouts are exceptionally enthusiastic radio fans, so the contest is sure to create unusual interest. In all probability prizes will be offered for the best receiving set constructed by a Boy Scout. Also another prize for the smallest set exhibited.

The Crocker-Wheeler Co., of Ampere, N. J., has given the Brooklyn Contractors a motor generator for the operation and transmission. These are the motors used by the United States Government on its aircraft and ships. The motor will be seen working at the show and at the end of the exhibition, it will be awarded as a prize in another amateur competition.

There is being built on the roof of the Ice Palace, located at the corner of Atlantic and Bedford Avenues, a 2,400 foot antenna. It will be the longest in the city. The antenna will be used for receiving and sending messages during the exhibition.

It is planned to have Mayor Hylan open the show. He will do it by radio either sending his opening message from the exhibition or sending it from a broadcasting station so that it may be picked up and heard by all at the opening of the show.

Uses for Radio Outside of Entertainment Are Cropping Up Steadily

Aside from the entertainment features of radio, many new uses are being found for this comparatively new development. Recently, persons on the streets of one of our large cities were astounded to see an automobile unoccupied, and apparently undirected, proceeding under its own power through the traffic, uncannily stopping, starting, turning out, honking its horn, and acting precisely as if guided by an invisible driver. And so it was, the real driver being in another car some distance away and directing it by wireless.

The same application can be made to boats and to airplanes, and progressive fire chiefs are experimenting to determine the possibilities of controlling fire-fighting apparatus by some similar method which will lessen the danger to firemen, and make it possible to place the fire apparatus closer to the vulnerable points in the conflagration.

Among those endeavoring to find wider uses for wireless are Assistant Fire Chief James E. Granger of Cleveland, Ohio; Chief Moran of the Hartford (Conn.) Fire Department, and Superintendent Garrett of the fire-alarm signal department of Dallas, Texas.

Superintendent Garrett has a radio receiving set installed in his automobile, and by this means is kept informed of every fire alarm, no matter where he may be at the time.

During the recent primary election in Pittsburgh the principal candidates gave short addresses over the radiophone, this being the first instance of its use for such a purpose.

When Gypsy Smith, the great evangelist, was holding a series of meetings in conjunction with the forty-eight Pittsburgh churches, these services were broadcasted over the radiophone by K. D. K. A. An enterprising publicity man installed a radiophone in the Gypsy's apartments at the Schenley Hotel, and surprised him with the phonographic production of his own voice from the radio station, seven miles distant, and also the singing of his own choir of over a thousand voices from the Motor Square Garden, two miles away.

Radio Corporation Offers Statement on Supply Situation

The question of radio supplies agitates a great many people at present, since so many of the radio enthusiasts often find it impossible to satisfy their simplest needs. The cause is, of course, the totally unexpected size of the demand for such equipment and the inadequate preparation for supplying it under which the manufacturers all labor. The following official statement by the Radio Corporation of America is of timely interest, implying as it does that that company and its associates are in the midst of a manufacturing programme which will not cease until the necessary apparatus is readily available. The statement is signed by E. E. Bucher, sales manager of the corporation:

"The Radio Corporation of America is endeavoring in every way possible to meet the unprecedented demand for radio devices, including vacuum tubes, broadcasting receivers, and other equipment, which has recently met with much response, not only on the part of the amateur and experimenter, but also on the part of a great many people who are interested to equip their homes with suitable radio telephone devices for receiving music, concerts, lectures, and other interesting features transmitted from radio telephone broadcasting stations.

"The factories of the General Electric Company and of the Westinghouse Electric and Manufacturing Company, which are manufacturing such devices for the Radio Corporation of America, are now operating on a greatly expanded production programme, and it is expected that within the next few weeks considerable quantities of material will be shipped to us on orders already placed with the factories by the Radio Corporation. These will be delivered to our customers as rapidly as received in the warehouse.

"Distributors are requested to communicate the above information to dealers, and to inform them that orders will be filled by us just as promptly as possible. This applies to all classes of radio apparatus for which we are accepting orders, including radiotrons, vacuum tubes, etc., which are employed for reception.

We believe that radio broadcasting is here to stay. The great opportunities for the sale of radio devices can, in our judgment, only be properly taken advantage of if all those who are interested in distributing and selling this apparatus properly equip themselves to handle this class of merchandise in a satisfactory way. This means that the dealer, or whoever is effecting the sale to the consumer, must familiarize himself with the product, explain its capabilities as well as its limitations, and lend assistance in every way toward the proper installation and maintenance of radio sets.

"Those who desire radio equipment and cannot for the moment obtain it, should be informed that the present shortage is but temporary, and due entirely to the great demand which suddenly came as a result of broadcasting, and that the Radio Corporation and its associates, the General Electric Company and the Westinghouse Electric and Manufacturing Company, are doing everything in their power to produce the necessary apparatus with maximum speed; that normal production is expected to begin within the next few weeks, and that deliveries will then be promptly made.

"A new catalogue covering all of the radio devices being manufactured for the Radio Corporation of America by the General Electric Company and the Westinghouse Electric and Manufacturing Company is now in course of preparation, and it is expected that it will be available for distribution within thirty to forty days from date. This catalogue will contain information of value to the wholesale distributor, the retail dealer, and the ultimate user of radio apparatus.

"We solicit your co-operation, and at the same time ask your indulgence until we have obtained factory production which will enable us to meet the demand."

Radio on Mail Planes

One of the big air mail ships came over from Chicago to Washington April 15 in the flying time of 6 hours and 2 minutes, piloted by E. Hamilton Lee. The mileage was 715 miles, which averaged 119 miles per hour. This ship came here for the purpose of having installed as a part of its equipment the radio sending and receiving telephones. This is the first of the transcontinental ships to be equipped with this wireless telephone-outfit. It is expected to equip all of the air mail ships with these instruments. The radius is 200 miles. With this wireless telephone equipment attached to the airships the pilot will be in constant touch with the station just left and the one to which he is flying. There will also be a range finder to locate the station toward which he is flying during foggy and stormy weather.

What Is Your Problem In Commercial Aviation?

GETTING STARTED?	All right, we have a stock of Airplanes and Motors ready to fly.
KEEPING GOING?	We can help you because we are the largest commercial aviation supply house in the country.
SERVICE?	Johnson Service means good service, including a modern equipped flying field and shop.
INFORMATION?	Our information department is at your service free of charge.
PRICES?	Lowest prices consistent with best material.
GUARANTEE?	Our customers must be satisfied always, or their money refunded.

Let us solve your problems in commercial aviation. Write us first and avoid costly delays. Our new catalog mailed on request.

A FEW SUGGESTIONS TO MAKE YOUR PLANE LOOK SNAPPY:

New Flottorp propeller, copper tipped $30.00
New radiators, Curtiss or Standard 20.00
New upholstered wicker seats 3.00
New side cowl or cock-pit cowl Curtiss or Standard 15.00
New streamlined wheels, 26x4 ...... 10.00
New Goodyear cord tires, 26x4 ...... 10.00
New fuselage covers, ready to put on, Curtiss or Standard $15.00
New wind shields 2.50
New shock absorbers, per foot ...... .05
New safety belts, American type 3.00
New center section with fittings, for Standard 10.00
New hose connections, all types ...... .10
New hose clamps, all sizes ...... $ .10
New Hartzell propeller, new design, brass tipped 60.00
New Warner tachometer with shaft 6.00
New thermometer, 15 ft. tube 7.50
New altimeters, 20,000 foot, luminous dial 10.00

Learn *to* Fly

Aviation is making such strides that it needs more men right now

You Can Learn To Fly

I can teach you how to become a successful pilot in a short time. My course is so arranged that you get only the things you need to make you a good aviator.

The Diggins Extension Course

is up-to-date, teaches you what you must know to become an expert flyer. This course is written by competent instructors right on my flying field. It is kept right up to the minute—all new developments in aviation are included. That is why it is recognized as the most complete and practical course offered today. My course saves you time and money because it prepares you at home so that you are ready to begin flying the day you arrive at the flying school.

Superior Points of the Diggins School

1. The Diggins school is the oldest, largest and most complete commercial aviation school in America.
2. The Diggins school is located in Chicago, the center of Aviation.
3. Living quarters and free employment service are maintained for students.
4. Diggins guarantees to make you a pilot.
5. Diggins' pilots get top notch salaries.
6. References, any aero club in America.

WRITE TODAY Write today for the new Diggins beautifully illustrated catalog.

to France in commercial air transport, but the English service is limited to regular daily trips between London and Paris. Other journeys are arranged according to demand.

The British commercial air subsidy for 1922 is £200,000, or about $900,000, half of it to be used for new planes available to operating companies on a hire basis. Dutch, Belgian and German commercial air schedules dovetail into those of French and British companies, making a fairly complete network over the whole continent with the exception of Russia and points in the extreme southeast of Europe.

From London to Paris by rail and boat the fare is $18.93 and the traveling time 6 hours and 30 minutes. The trip by air costs $30.66 and the traveling time is 1 hour and 45 minutes. For a trifle more than one and one-half times the railway fare the trip can be made by air at a saving of four hours and forty-five minutes in time.

In other instances air travel is more expensive. The trip from Nimes to Nice, in southern France, costs $30, which is at the rate of just about three times the mile charge from Paris to London.

Notwithstanding this regulation of air tariffs, according to the exigencies of competition rather than the value of service rendered, air transport in Europe is being developed for the most part on strictly sound principles. Just enough Government encouragment is given to keep the spark of ambition from being smothered under unavoidable financial losses due to the hazards of this new common carrier enterprise.

—*Editorial in N. Y. Herald.*

in air since the model was placed upside down, thus reversing the buoyancy.

APPENDIX

Strength of Crow's Foot

A test was made to determine the strength of a crow's foot such as is used to fasten the ropes on airships and furnished by the Goodyear Rubber Company. The arrangement on the apparatus was as shown in Fig. 2. The small ropes of the crow's foot were fastened to the floor by means of a rope, and the fabric pulled upward by means of a chain hoist. Suspension scales between the crow's foot and the hoist were used to determine the force exerted. The apparatus was tried without the wood frame work about the iron pipe at first, and it was noticed that the middle fingers were taking by far the greater part of the load due to the bending of the pipe. In order that all four fingers might be stressed to more nearly the same degree the wood frame was made so that it supported the pipe at all points, and with a piece about 1¾ inches by 2½ inches across the back, as shown in the rear view to prevent the ends being bent toward each other. However, even with this arrangement, it was noted that the two middle fingers were under greater stress than the others.

Failure occurred at 1125 pounds which gives, when the weight of the frame is subtracted, practically 1100 pounds. The fibers of the rope held securely, and it was only the fabric at the ends of these fibers which gave way.

Tests to determine the strength of small crow's feet (about 3 inches $\times$ 3½ inches) were also made. These were cemented to the fabric of the large crow's foot, and weights applied until failure occured. Seven tests were made and failure occured at the following loads:

No. of Test	1	2	3	4	5	6	7
Load (in lbs.)...........	190	190	185	185	200	180	180

Average load = 187 pounds.

The time taken on each test, except No. 7, was about 10 minutes. In No. 7, a load of 160 pounds was put on and left for about 20 minutes, in order to ascertain roughly if time was an important factor. In this test practically all the strands of the cords pulled out, whereas in all the other tests, except No. 6, only part of them pulled out while the others broke, the number which broke varying from 1 to 3.

Digitized by Google

The plane whose remarkable performance, rugged strength and unbelievable economy of operation have brought immediate recognition and success.

It takes off in less than 150 feet and lands at 33 MPH with a load of 736 pounds.

The Vital Requirements of Pursuit Engines

LOW FUEL CONSUMPTION

(Fourth of a Series)

Low fuel consumption in pursuit engine performance is a vital necessity. A greater travel radius, an increased useful load and a greater economy in operation are among its several advantages in effective operation. This organization in carefully weighing these advantages has deliberately designed and built the Wright Pursuit Engine, the only proved pursuit engine in the world which is in production today, to give the very highest effective performance with lowest possible fuel consumption.

Pilots!

will tell you.

From long and successful experience in flying they know that good commercial aeroplanes must combine

RELIABILITY
STRENGTH
PERFORMANCE
ECONOMY
COMFORT

This knowledge on the part of pilots explains why the best and most successful flying organizations in America are today using Curtiss Aeroplanes and Motors.

And because we know what the successful pilot needs and insists on, we have built into every Curtiss Aeroplane these essential requirements.

This is made possible by our unsurpassed facilities for scientific research and study of aeronautical problems.

Without access to such facilities aeroplanes must be built by guesswork.

USED JN'S FROM $650 UP

Watch this space for list of America's best and most successful flying organizations. Of course they use and sell Curtiss Aeroplanes.

Commercial Flying Becoming Safer

RECENT accidents in the air may damage commercial aviation unless the public realizes that most of these are the result of the more dangerous military flying or of the use of obsolete aircraft which should be banished from the air by legislation, Grover C. Loening, president of the Aeronautical Chamber of Commerce, said recently.

Mr. Loening pointed out that commercial machines operated by reliable companies are equipped with a new type of wing section that does not stall in the air. None of the machines in recent crashes were equipped with these.

"While these new types of wing sections are not so applicable to military machines because they reduce the quickness of maneuvering and make a tail spin difficult, nevertheless they are essential on a safe commercial machine because a stall, instead of becoming a dangerous feature, results merely in the plane's settling on a level keel without losing its controlling power," he said.

Mr. Loening pointed out that there are countless rules and regulations for ships and mariners, but as yet practically none for planes and airmen.

"The progress already made in Congress in connection with the Wadsworth bill for a bureau of civil aeronautics in the Department of Commerce shows that there is already a general appreciation of another large group of causes of aviation accidents that can be eliminated. That is the flying on dangerously weakened and old, unfit aircraft, and also by operators of aircraft who are unlicensed or otherwise unsuited to perform the expert and professional duties of an air mariner. Regulation of commercial aviation by law is one of the greatest needs of commercial aviation today. The advantage of such regulation is brought out by the very small number of accidents during the year occurring in Canada, where operators and aircraft are inspected and licensed."

As examples of the safety of commercial aviation properly controlled Mr. Loening pointed to the air mail service, which has been operating daily from coast to coast without an accident in the last forty weeks, and the Aeromarine Airways, which has carried thousands of passengers in safety.

New Use for Planes

AEROPLANES have been used for fighting, bombing, racing, freight carrying, mail carrying, controlling forest fires, gasing caterpillars and other insects, hunting seal herds, locating schools of fish, mapping unknown country, photographing impenetrable swamps and doing hundreds of other jobs, but now they are to be used to track the spread of that most destructive parasite, black stem rust, which destroys one or two hundred thousand bushels of wheat yearly on this continent.

The theory of the Department of Agriculture is that the spores of the black stem rust are carried north to the wheat belt in currents of the upper air. Dr. Stakman of the bureau of plant industry of the Department of Agriculture, in cooperation with officers of the engineering division of the Air Service at McCook Field, is designing spore traps to test this theory. Aeroplanes will carry these traps to great heights, and on opening them at previously determined altitudes will be able to collect the spores carried in the air at various heights and in various wind currents. Once the spore's means of travel and point of origin is determined it can probably be eradicated.

Science and Fire Fighting

THE picture Chief Kenlon recently drew of the Fire Department of the future is all the more interesting because it is so likely to become reality soon. John Kenlon is no visionary, after thirty-five years of the fire fighting game, and when he sees fire engines on the roofs of buildings, helicopters dropping gas bombs on blazes and fire alarms sent by radio it is reasonable to predict that New York will see these improvements, at least in the downtown district, within twenty years.

The war showed, although in a horrible way, the utility and power of gases and chemical liquids. The ingenuity that was employed in destroying life should easily be turned to the more laudable purpose of saving property. If the sprinkler pipes in business buildings should be emptied of water and refilled with some gas which would extinguish fire without damaging floor or goods the saving would be great.

The firemen of the next generation may make his heroic rescues not from a swaying ladder but from a purring aeroplane.—Editorial in *N. Y. Herald*.

THE NEWS OF THE WEEK

National Advisory Committee for Aeronautics Meets

Washington.—A complete and detailed study of the plans and specifications of the Navy's giant Airship ZR-1 was requested of the National Advisory Committee for Aeronautics at its session April 20 by Rear Admiral Wm. A. Moffett, Chief of the Naval Bureau of Aeronautics. Before the rigid airship, whose parts are now being fabricated, but which had not yet been assembled, is completed, Admiral Moffett is desirous of having a thorough study made of all the stresses and strains it is likely to encounter in the air under service conditions and it is for this reason that he has asked the Committee to appoint a special technical subcommittee of aeronautical experts and engineers to make a special study of its design and structure. While the Navy is confident that its own plans for the airship are correct, it is nevertheless desirous of securing the opinion of an independent committee of experts to avoid the possibility of future adverse criticism. The whole committee approved Admiral Moffett's request and authorized its Chairman, Dr. Walcott to appoint a special technical subcommittee for this purpose.

The session of the National Advisory Committee today was the first meeting of the year of this group of twelve government and civilian experts on aeronautics and kindred subjects, operating as an independent government establishment reporting directly to the President, and co-operating with the Government Departments interested in aeronautical development.

Dr. J. S. Ames, Chairman of the Executive Committee, reported on the progress made at the Committee's research laboratory at Langley Field in the development of a new heavy-oil, fuel-injection aircraft engine for the Bureau of Aeronautics, Navy Department. While the details of the development are still held confidential, it is known that its use will greatly reduce the fuel fire hazard in aircraft, which has been largely responsible for the loss of life in recent aircraft accidents. A large percentage of aeroplane fatalities are due to gasoline fire following the crash. This new engine not only does away with the use of gasoline, but also operates without carburetor and spark plugs, thus eliminating certain causes of trouble.

Drawings and performance characteristics of a new high-speed aeroplane wing, just developed at the Committee's laboratory, Dr. Ames stated, have been turned over to the Army Air Service for use in the design of a new high-speed pursuit type aeroplane. This new wing is a thick wing section with space for internally bracing the wing and eliminating any wires or struts in the design of the aeroplane. The wing is both tapered in section and in plan form, conforming somewhat to the general shape of a bird's wing, that is, tapering toward the tip, both of which add materially to the speed charcteristics of the wing.

Dr. Ames also explained the operation and application of three new recording instruments recently developed at the Committee's laboratory for studying the performance not only of the aeroplane itself in flight, but the actual conduct of the operator. The instruments are a new type of recording accelerometer, and instrument for recording the positions of the aileron, rudder and elevator in maneuvering the aeroplane. The use of these instruments, together with a recording air speed indicator, gives a complete history of the loads induced in an aeroplane when maneuvering or landing, together with the range of operation of the aeroplane controls. The information obtained is not only of great value to the designer but also will be very helpful in instructing pilots in the proper use of the controls when carrying out maneuvers.

The meeting was presided over by Dr. Charles D. Walcott, Chairman of the National Advisory Committee for Aeronautics, and Secretary of the Smithsonian Institution. Mr. Paul Henderson, the newly appointed Second Assistant Postmaster General, in charge of the Air Mail Service, was present on invitation. The other members of the Committee present were:

Dr. Joseph S. Ames, Chairman Executive Committee; Dr. S. W. Stratton, Secretary; and Director, Bureau of Standards; Major General Mason M. Patrick, Chief of Army Air Service; Rear Admiral William A. Moffett, Chief of Naval Bureau of Aeronautics; Rear Admiral D. W. Taylor, Chief Constructor, U. S. Navy; Professor Charles F. Marvin, Chief of the Weather Bureau; Dr. John F. Hayford, Northwestern University, Evanston, Ill.; Major Thurman H. Bane, Chief of Engineering Division, Army Air Service, Dayton, Ohio; Dr. Michael I. Pupin, Columbia University, New York City; Mr. Orville Wright, Dayton, Ohio.

Mr. Orville Wright and Mr. G. W. Lewis, Executive Officer of the Committee, leave Washington tonight for Langley Field, Va., where they will make an inspection of the Committee's laboratory and the research work in progress.

Woman Flies 400 Miles to Do Spring Shopping

Chicago.—Mrs. C. E. Tuttle, of Red Oak, Iowa, came to Chicago April 20 by aeroplane to do her spring shopping. She arrived with her shopping list and an overnight bag after piloting her plane over the 400-mile route from Red Oak to this city in four hours and fifty-five minutes. A mechanician accompanied Mrs. Tuttle.

Mrs. Tuttle is the wife of a business man in Red Oak.

New Round-World Flight by British

London.—Plans are well advanced, says the London correspondent of the Yorkshire Post, for another British round-the-world flight but the date of the start has not been fixed.

All preparations have been made by a flying man of much experience and he will pilot the machine. At present he holds a civilian appointment at the Air Ministry and has been given all possible official aid.

A specially designed flying boat of huge dimensions is to be used. The crossing of the Atlantic will be the first stage, starting from Lisbon and taking in the Azores.

The Late Sir Ross Smith

London—Sir Ross Macpherson Smith, on the eve of his orojected flight around the world, was killed in the presence of his brother, Sir Keith Smith, at Brooklands, April 13, while he was testing the Vickers-Viking machine in which he had planned to make the world circuit. Sergt. J. M. Bennett, M. S. M., the mechanician, who accompanied him on his famous flight to Australia in 1919, was also killed in the crash.

For half an hour before taking up the machine himself, Sir Ross had been in the machine while Capt. Cockerell, of Vickers, Ltd., put her through her paces, during which the Viking behaved beautifully. On descending, Capt. Cockerell handed over the machine to Sir Ross, who, amid shouts of applause from the spectators, made a fine take-off. His brother, Sir Keith, was delayed in reaching Brooklands and so was unable to accompany the intrepid flyer.

For fifteen minutes Sir Ross put the machine through the ordinary flying test. Then he prepared to descend. When about 1,200 feet from the ground he shut off the engine. Almost immediately she began a nose dive, and as the efforts of her pilot to right her failed, she made a spinning nose dive.

Gathering terrific speed as she neared the ground, she smashed to pieces on the fence surrounding the Brooklands automobile race track. Sir Ross was lifeless when lifted from his seat, and Sergt. Bennett, sitting beside him, died a few minutes after being extricated.

No other flight had ever been so carefully thought out. Months ago all the proposed landing fields over most of the 21,000-mile trip had been closely inspected. All the gasoline depots had been planned. It was to have been the crowning achievement of his flying career and Sir Ross had every confidence that he would succeed.

The Viking's gasoline capacity was 385 gallons, giving an estimated range of more than 1,700 miles. It was fitted up with a motion picture camera and sending, receiving and directional wireless apparatus. There were to have been fifty pounds of engine spare parts aboard, and Sir Ross and his companions were to have limited their personal apparel to eight pounds each. Two revolvers, a Winchester rifle and some fishing tackle were to have been carried.

R. K. Pierson was the designer of the Viking. He also designed the machine in which the flight was made to Africa in 1920, the Vickers-Vimy, in which the late Sir John Alcock and Sir Arthur Whitten Brown flew across the Atlantic, and also the machine in which Sir Ross Smith made his 11,294-mile flight to Australia in a little less than twenty-eight days. It was the latter achievement which induced King George to confer knighthood upon the two Smith brothers.

Personal Par

Roger Q. Williams, pilot, plane changer and aerial acrobat, who has been identified with aviation for a number of years, announces that he has given up exhibition work and is using his planes to aid The Jensen Specialty Corporation, of Los Angeles, Cal., in marketing their products. Friends will recall his work with the following circuses: World's Famous Trio, Tinney Fearless Flyers, Sammie Harrell Flying Circus, Sikeston Aerial Corporation, and the Roger Q. Williams Famous Flyers.

The AIRCRAFT TRADE REVIEW

Curtiss Aero Profits

The Curtiss Aeroplane and Motor Corporation for 1921 reports gross profits on sales of $578,118, and net profits, after all selling expenses and subsidiary company losses, of $277,466. After allowing for interest charges depreciation, etc., there was a net surplus for the year of $101,207. The balance sheet at the close of the year showed a profit and loss deficit of $1,158,924.

C. M. Keyes, President, in remarks to stockholders said that on Dec. 31, 1921, the company had Government contracts on hand amounting to $1,763,224, "which is sufficient to operate the factory at Garden City and part of the factory at Buffalo. A large percentage of the factory at Buffalo is leased to other manufacturers on a floor space basis."

A. C. C. Joins U. S. C. C.

We are pleased to advise you that the Aeronautical Chamber of Commerce of America has been admitted as a member of the Chamber of Commerce of the United States, the national organization which includes some 1200 or 1500 commercial and civic organizations throughout the United States.

Palm Beach-New York Rapid Flight

Flying at an average speed of 130 miles an hour through three storms, a Loening Air Yacht, carrying a total load of 1,600 pounds, made the flight from Palm Beach, Fla., to New York, a distance of 1,210 miles, in nine hours and fifty-six minutes. Railroad time between the two points is forty-eight hours.

One stop was made, at Southport, N. C. The flyers took off at Southport landing at the Columbia Yacht Club, in the North River, New York City. Clifford L. Webster, former United States Marine Corps aviator, piloted the seaplane, and claimed to have established a time record. Fred R. Golder, of Port Washington, L. I., mechanician, accompanied him.

Webster's machine is the altitude record holder for seaplanes, having taken four passengers a height of 19,500 feet at Fort Washington on August 16, 1921.

Webster said that on several occasions he was compelled to fly as low as twenty feet above the surf to escape dense fogs. Clouds and fog, he said, compelled him to guide his course across Pimlico Sound, North Carolina, and Chesapeake and Delaware bays by compass. The average height at which he flew, the pilot said, was 1,800 feet.

The air yacht in this record flight is of the type recently purchased by Vincent Astor, who has retained Webster as his pilot. Webster was Mrs. Astor's flight instructor at Bay Shore before the war.

Grover Loening, designer and builder of the air yacht, said that he did not regard the flight as indicating that ten-hour trips between Riverside Park and Palm Beach would be common incidents for a year or two yet. But it did indicate, he said, that this particular kind of flying was the safest that could be undertaken.

Learn to Fly

The Dayton-Wright Company, of Dayton, Ohio, have just gotten out a little booklet, "Learn to Fly," which should be in the hands of everyone contemplating a flying course. The Dayton-Wright "Chummy," which is used exclusively in the school, is properly illustrated.

Baltimore to Hold Air Meet

Every year since the close of the war the Baltimore Flying Club has held an aviation meet or, as it is now called, an Exhibition of Aircraft. Each year's meet so far has proven to be a bigger success than the last. In 1919 there were hardly a half dozen ships on the field; in 1920 there were twelve or fourteen and the meet lasted an entire week. This, however, did not prove satisfactory for in 1921 the Club went back to the single day meet and drew the largest crowd they had up to that time, while the exhibiting ships numbered about twenty-five including commercial planes, sport planes, Army planes and National Guard planes.

A departure is to be made this year in having an event for water ships, that is, seaplanes and flying boats. This is easily possible for Logan Field, as the Club's beautiful and well kept airdrome is within a few hundred yards of the Patapsco River, a wide and well protected landing harbor.

The principal event, however, will be for land planes and the contests will be divided into four classes e. g. (1) for commercial planes designated as ships carrying useful load of 750 lbs. or more; (2) for sport planes which includes all one, two and three seaters; (3) for service pilots, Army pilots, Navy pilots and Marine Corps pilots and (4) for National Guard pilots.

For the first time prizes will be awarded but they will not be for speed or high altitude but rather for efficient design and precision flying. This does not mean there will be no speed races, for there will be several, but rather that speed will be secondary to speed range.

It is expected that practically all the entrants at the New York show to be held April 30th will remain over for the Baltimore event and a number of additional commercial entries will be received from the middle west.

The Air Service will send ships from Bolling Field, Langley Field and Aberdeen.

Aerial Lighthouse Established at American Airways Base

American Airways, located at College Point, Long Island, announce the establishment of a highpowered searchlight to be maintained as an aid to aviators. The light will be a 14-inch lens Navy type, and will be thrown at an angle of about 50 degrees elevation, pointing due North. The character of the light, whether a flashing or fixed beam has not yet been decided by the Harbor Commissioners of New York. Announcement of their decision will be made in a later issue.

The light will be visible from sunset to midnight every night, as there are always a number of late flyers coming in down the Sound during the summer months. The base of American Airways is always available for itinerant craft, and mooring and watchman service are available, in addition to regular 'aerial garage' service, such as emergency and permanent repairs, overhauls, etc. The base is equipped to do work of whatever character may be required, being completely equipped.

American Airways have recently been made Curtiss representatives and maintain several machines for demonstration and joy-ride purposes.

Experimental work is going forward on a patent contracting wing, and an all metal amphibian scout.

The Trading School for Aeroplane Mechanics is continually getting new students and those who have been here for some length of time are becoming most proficient in their work. Several ships have been rebuilt this spring, and several others sold. A large number of applicants for the Pilot Training Course recently in in response to advertisements in this publication. The response has been most encouraging.

Spokane News

Spokane, Wash.—Six hundred feet of aerial moving picture films of the Columbia Basin project will be taken by the United States Aircraft corporation.

"Under present plans, our big new six-cylinder Spokane motored ship will leave here and will be equipped with the latest Akeley aviation motion picture equipment," Mr. Messer said. "Upon our return here the films will be turned over to the Columbia Basin committee for use in exploiting the work.

"In addition to the moving pictures, we will take 'stills' at different points along the way. This new ship is especially equipped with a large roomy cockpit for picture making. We have a quick-focus camera mounted on a universal table."

According to present plans the ship will go to the Ephrata district and take pictures over the southern part of the district. Later pictures of the remainder of the entire project may be taken.

A Correction

The following letter is self-explanatory: "Thank you very much for putting me on the cover of your April 10th issue. I am sorry, however, that you called it the SPERRY MESSENGER, as it gives the impression that we are responsible for the design of this remarkable little plane. I wish to correct this wrong impression, as you know that the machine was designed by the Engineering Division of the U. S. Air Service at McCook Field, Dayton, Ohio, which is under the splendid guidance of Col. Bane. Mr. A. G. Verville is responsible for the design, and Col. Guy L. Gearhart fathered the proposition and made a great many valuable suggestions."—*Lawrence B. Sperry.*

NOTES ON LANDING PLACES FOR SEAPLANES ALONG THE ATLANTIC COAST

Prepared by EWING EASTER

For the National Advisory Committee for Aeronautics

New Jersey

Asbury Park.—Emergency landing for small craft only in Deal Lake. Deal is an artificial lake about a mile long and about 150 yards wide. Several bridges and telephone wires make landing and take-off dangerous. Protected anchorage anywhere. Gas and oil available. No aviation supplies. No beach. No tide. No current.

Keyport.—Excellent landing for all seaplanes. Moorings in deep water furnished by Aeromarine Plane and Motor Corporation, who have large factory there. Repairs and supplies available. High test gas and oil at factory. Three to four foot tide. Beaching facilities.

Delaware

New Castle.—Landing for all seaplanes. No protected anchorage. No beach. Swift current around wharves. Gas and oil available. No aviation supplies. Tide 5 to 7 feet.

Maryland

Annapolis.—Excellent landing for all seaplanes. Good sand bottom and beaching facilities at north end of state road bridge. Annapolis one mile from this point. Weather reports available at Naval Academy. Gas and oil available. No aviation supplies. One foot tide. No current.

Baltimore.—Excellent landing for all seaplanes at Hanover Street Bridge, which can be seen from the air as large concrete bridge south of upper Baltimore harbor. Protected anchorage furnished by Easter Airlines, whose shop and office are located in arch of bridge. High test gas and oil. Aviation supplies and repairs available. One foot tide. Beaching facilities. No current. Ten minutes from business district by trolley. Weather reports available.

Cambridge.—Good landing for all seaplanes. Protected anchorage with firm sand bottom in cove west of steamboat landing. Good beach about one mile west of town. High test gas and oil from Red "C" Oil Company. No aviation supplies. Two foot tide. No current.

Chestertown—Good landing for all seaplanes. Partially protected anchorage with mud bottom near bridge. Beach on opposite shore from town. Gas and oil available. No aviation supplies. No tide. Moderate current.

Crisfield.—Good landing for all seaplanes. Protected anchorage in creek west of town, with firm sand bottom. No beaching facilities. Gas and oil at public wharf. No aviation supplies. Two to four foot tide. No current.

Easton.—Good landing for all seaplanes. Large craft will land at mouth of Tread Avon River and taxi to steamboat wharf at Easton Point. (One mile from town.) Gas and oil available by truck from town. No aviation supplies. Tide negligible. Moderate current.

Ocean City.—Excellent landing for all seaplanes in Sinepuxent Bay. Good anchorage with sand bottom near bridge. Good beach. Gas and oil available. Two foot tide. Strong current at bridge and wharves. No aviation supplies. Weather reports at Coast Guard Station.

Oxford.—Good landing for all seaplanes. Good anchorage in firm sand. Beaching facilities. Gas and oil available. No supplies. One to two foot tide. No current.

Salisbury.—One-way landing and take-off for small craft only in Wicomico River. Very narrow and twisting. Landings will be made at point in river two miles southwest of town and taxi up to public wharf. *No landing for large craft.* Anchor-in soft mud bottom. Gas and oil available. No supplies. No beach. No tide. No current.

Cape Charles.—Good landing for all seaplanes. Avoid stakes and keep in steamboat channel when taxiing up to wharf. Protected anchorage with sand and shell bottom in cove near steamboat wharf. Gas and oil stations on docks. Three foot tide. No supplies. No beach. No current.

North Carolina

Beaufort.—See Morehead City as landing facilities are much better there.

Columbia.—Good landing for all seaplanes in Bull Bay which is three miles from town. In taxiing up Suppernong River avoid stakes and keep in channel. One-way landing and take-off for small craft in Suppernong River nearer town. Protected anchorage with soft mud bottom. Gas and oil available. No beach. No supplies. No tide. Moderate current.

Bell Haven.—Good landing for all seaplanes. Anchorage for large craft in front of town. Protected anchorage for small craft in creek in back of town. Gas and oil available to wharf by truck. No tide. No current. No beach. No supplies. *Avoid submerged reef marked by Wreck East of public wharf.*

Edenton.—Good landing for all seaplanes. Protected anchorage with soft mud bottom in creek west of public wharf. Gas and oil available. No beach. Two to three foot wind tide. Moderate current. No supplies.

Elizabeth City.—Good landing for all seaplanes. Protected anchorage in harbor, with mud bottom. Gas and oil available at public wharf. No aviation supplies. No tide. No current. No beach.

Hertford.—Good landing for all seaplanes. Avoid stakes in landing and taxiing. Protected anchorage with firm sand bottom. Gas and oil available by truck. No supplies. No tide. No current. Good beach.

New Bern.—Good landing for all seaplanes. Unprotected anchorage with firm sand and mud bottom. Severe northeast gales frequent between November and April. Gas and oil available at public dock. No supplies. No tide except wind tide. Moderate current. No beach.

Oriental.—Good landing for all seaplanes. Protected anchorage, with firm sand botom. Gas and oil available from garage in town. One to three foot tide. No current. Good beach.

Plymouth.—One-way landing and take-off for small craft only. *Not safe for large craft. Dangerous as river is narrow and bordered with high trees.* (Width of river about 200 feet.) Protected anchorage with soft mud bottom. Gas and oil available. No supplies. No tide. Moderate current. No beach.

Morehead City.—Excellent landing for all seaplanes. Unprotected anchorage in front of city. Gas and oil available at gasoline docks. Weather reports and aviation supplies available from Coast Guard Air Station two miles south of town. Also beaching facilities there. Four to five foot tide. Swift tidal current at wharves.

Southport.—Excellent landing for all seaplanes. Unprotected anchorage, rocky bottom. Gas and oil at wharf. Two foot tide. Beach. No supplies.

Swann Quarter.—Good landing for all seaplanes in Juniper Bay. Seaplanes will beach at entrance of canal one-half mile from town. Protected anchorage with firm sand bottom. Gas and oil supplies not always available. One to two foot tide. No aviation supplies. Good beach. No current.

Washington.—Landings for large craft will be made east of railroad bridge about one mile from city. Landings for small craft can be made in front of city between bridges. In landing here avoid small stakes. Gas and oil for large craft by truck from city, for small craft at gasoline docks. Good anchorage, mud bottom. No tide. No beach. No supplies.

Wrightsville Beach.—Landing for all seaplanes in sound north of bridge. Take-off along sound to north or through inlet to ocean. Numerous sand bars to be avoided. Unprotected anchorage in sound with sand bottom. No gas and oil except by trolley from Wilmington during winter months. Gas and oil available in summer. Trolley service to Wilmington all year. Two to four foot tide. Swift tidal current. Good beach. No aviation supplies. This is the best point of landing for Wilmington as the river at that point is narrow with submerged stumps and exceedingly swift current.

Wilmington.—See above.

South Carolina

Beaufort.—Landing for all seaplanes. At high tide avoid submerged reef and marshland extending about one-quarter mile out from point of land on opposite shore east of town. Moorings available in front of K. of C. wharf. Good anchorage here also with firm sand bottom. Gas and oil station on steamboat wharf. Aviation supplies available and beaching facilities at Marine Air Station, Paris Island. Four to six foot tide. Strong tidal current at wharves.

Charleston is marked on your map so I presume you have full data. Paris Island is also marked on your map.

Georgetown.—Good landing for all seaplanes in Winyah Bay and taxi quarter-mile up creek to town. Anchorage at mouth of creek with firm sand bottom. (Do not anchor in creek in front of town as bottom here is smooth rock.) Gas and oil

Digitized by Google

available at wharves. No supplies. Two foot tide. Swift tidal current at wharves. Beach at mouth of creek.

Georgia

Savannah.—One-way landing and take-off for all seaplanes. Unprotected anchorage with mud bottom. Gas and oil available. No aviation supplies. Swift current. No beach. — foot tide.

Fairhope unsuitable for landing.

Darien unsuitable for safe landing.

Brunswick.—Landing for all seaplanes. Protected anchorage in front of abandoned Naval Air Station. Gas and oil available at public wharves. Tide three to four feet. Strong tidal current at wharves. Beach at Air Station. No supplies.

Fernandina.—Good landing for all seaplanes. Unprotected anchorage near mud flats opposite city. Protected anchorage in creek south of city. Severe northeast gales frequent from November to May. Gas and oil at gasoline docks. No supplies. Six to eight foot tide. Swift tidal current at docks. No beach.

Deland.—Landing for small craft only in Lake Breesford which is three miles from town. Protected anchorage anywhere with mud bottom. Gas and oil available at dock. No supplies. No tide. No current. No beach.

Note.—The St. Johns River route is unsafe for any but very small craft south of Lake George, as the river is narrow and very twisting.

Green Cove Springs.—Good landing for all seaplanes. Protected anchorage on either side of steamboat landing. Gas and oil available from garage by truck to wharf. One to two foot tide. No current. No supplies.

Palatka.—Landing and take-off for large craft north of railroad bridge or south of state road bridge. Landing for small craft between bridges for take-off in small bridge taxi through railroad drawbridge and take-off on north of same. Gas and oil available for large seaplanes by truck and for small craft at public wharf. No supplies. No beach. No tide. No current.

St. Augustine.—Excellent landing for all seaplanes north of bridge. Anchorage with mud botom anywhere in front of town. Protected anchorage and beach in creek at north end of town. Gas and oil available at Capo's wharf or from garages. No aviation supplies. Three foot tide. Strong tidal current at wharves. Weather reports from Coast Guard Station.

Sanford.—At head of St. John's River route for small craft Excellent landing. Protected anchorage with firm sand bottom near public wharf. Gas and oil available from garages. No beach. No tide. No current. No supplies.

Note.—I have operated an "F" boat at the points mentioned and this above report is based upon notations made at the time.

Latitude and longitude is not given as I have no means of ascertaining this data at hand.

In giving the rise of tide I have not taken the figures for mean neap tide but have given figures which allow for the maximum rise due to wind conditions, which are of more interest to the seaplane pilot.

SOME PRINCIPLES GOVERNING THE ESTABLISHMENT OF METEOROLOGICAL STATIONS ALONG AIR ROUTES*

By P. AUJAMES

Chief of the Radio Meteorological Service of the Compagnie Franco-Roumaine de Navigation Aérienne

The organization of a meteorological service for an air route involves the solution of two distinct problems:

1. Distribution and grouping of meteorological stations;
2. Communications.

Experience gained in the establishment of two lines, Paris-Warsaw and Constantinople-Bucharest** enables us to establish certain principles, which it may be of interest to note here.

I. Distribution and Grouping of Meteorological Stations

Before touching upon the study of this question, it is well to recall the principles for laying out an air route. When it is proposed, under existing conditions, to cstablish a regular airplane transportation service between two points 1,500 or 2,000 kilometers apart, it is out of the question, for technical and commercial reasons to fly the whole distance without landing.

Therefore the line is divided into sections of 400 to 500 kilometers, terminating in large cities. Aeroplanes traverse these sections in a single flight. Example: Paris-Strassburg-Prague-Warsaw.

Laying Out the Sections.—A section of an airway should not be regarded as a straight line between two cities (which would be a serious mistake), but as a passage-way from 50 to 100 kilometers wide, within which the actual track is determined by experience, that is to say, from a perfect knowledge of conditions in the regions traversed, thus assuring maximum safety by encircling obstacles, flying over the greatest possible number of landing fields, avoiding districts om meteorological disturbances, etc.

In aviation, a straight line is not the shortest distance between two points, for example: Constantinople-Bucharest by Adrianople and Giurgevo. On this route the itinerary followed by the aeroplane changes from day to day and from one part of the day to another.

The duty of the meteorological organization consists in supplying at any moment information enabling:

1. The departure of aeroplanes, when the atmospheric conditions are suitable for flying and landing with safety;
2. The determination of the path to be followed within the strip of territory constituting the section.

Meteorological Organisation.—Granting the above, the meteorological organization of a section comprises:

(a) The division of a section into a certain number of zones. These zones are portions of the territory with uniform climatic conditions. Examples: Champagne, Lorraine, the Bavarian platteau, Thuringia.

This division necessitates a very careful meteorological study. In each of these zones a variable number of meteorological stations will be installed.

(b) Types of zone meteorological stations, three types:

1. Central stations for collecting information and making soundings, and mountain stations;
2. Auxiliary observation stations.
   (a) Along the route.
   (b) For near lateral protection.
3. Stations for distant lateral protection.

Central Stations

These must coincide as much as possible with regular or emergency landing fields. In each section it is necessary to have at least as many stations of this kind (not including mountain stations) as the average number of hours of flight required for traversing the given section. A station of this type is also established on some summit in every mountainous region traversed. Such stations are provided with complete meteorological outfits. Their personnel comprises at least one meteorologist and one assistant. They can, in particular, make soundings with pilot balloons (or captive balloons). It is assumed that the wind direction and velocity are constant throughout the entire zone within which a station is located, as determined by the soundings.

These stations are connected with the auxiliary observation stations by some suitable means of communication.

Auxiliary Observation Stations

These stations should be located, some in quincunx formation relative to the median line of a section and at 40 kilometers from this line, the others (few in number) on the line itself.

It is a common error to wish to increase the number of observation stations on the direct line between two points on the map. This is a result of the error committed in defining the path of an air route and always results in limited information.

These auxiliary stations do not make soundings. Their only duty is to observe cloudiness and visibility. They do not require special apparatus or personnel. It is sufficient to have agents residing in the locality, such as teachers, customs officers, etc.

The aerial navigation companies have decided to maintain a complete system of these stations. Their distribution in quincunx alone enables the utilization of the meteorological information, even two or three hours after the observation. The fundamental difficulty encountered is that of communication. In the usual case of a wind blowing across the section, the lateral stations enable a fairly exact forecast of cloudiness and variations of visibility in the strip of land included in the

* From "Premier Congrès International de la Navigation Aérienne," Vol. I, pp. 115-119, Paris, November, 1921.

** French Aeronautic Mission in the Orieot.

Digitized by Google

section, and, consequently, the determination of the itineraries of the aeroplanes.

Stations for Distant Lateral Protection

In order to be able to make forecasts for periods of five or six bours and to protect the line against violent storms, it is necessary to locate meteorological observation stations at distances of from 110 to 150 kilometers from the line. These stations are selected from among those included in the meteorological organization of a country. Example: Line, Paris-Strassburg: Dijon-Mabeuge; Strassburg-Prague: Frankfort-Munich.

II. Communications

Since it is important to choose well the location of the stations, to group them in a proper manner and to make careful and frequent observations, it follows that the most difficult problem to solve in the organization of the air routes is the problem of communication. The value of the meteorological service depends on the efficiency of its lines of communication.

It is much less difficult to make observations, than to assemble ~~and make~~ prompt use of them. A meteorological report however, is really valuable only at the time of the observation.

It is necessary, therefore, to establish a very complete and perfect system of communications. This can only be brought about gradually. It is by constant effort, great patience and much expense that valuable results can be obtained.

The comunication problem consists of two parts:

(a) Assembling the information;
(b) Interpretation and use.

Assembling the Information

Central stations and mountain stations must be equipped with telephonic and radiotelegraphic systems of communication.

(a) Radiotelegraphy can alone assure sufficiently prompt transmission of information to the other central stations of the line. It alone enables the reception of information from these stations and from the stations for distant lateral protection.

Experience shows that aerial navigation cannot do without a specialized radiotelegraph system, which alone can assure a sufficiently rapid communication for the needs of air traffic and the meteorological service. Such a system is being created in France and in England.

The utilization of non-specialized telegraphic and radiotelegraphic systems in other countries is the source of great difficulties. Communications are intermittent and messages travel too slowly. Moreover, this expedient does not enable communication with aeroplanes.

(b) The principal and secondary stations are connected by telephone (except in special cases). It is necessary to obtain telephonic priority, which is very troublesome. The communications must be sent at a certain time for regular observations, aside from which they are only sent as exceptional messages, in case of storm warnings. It is important for these warnings to be transmitted as promptly as possible.

Interpretation and Use

Assuming that the information is brought together in the desired time, it is important to profit from it as much as possible. First it must be interpreted and then put to the best use. It is necessary for the contact between meteorologist and pilot to be close and constant. It must be recognized that the pilots are very skeptical concerning the accuracy of meteorological information. At the opening of a line, much patience is therefore required to win them over and obtain their confidence.

The meteorological information must be presented in as concise and simple a form as possible, easy to assimilate and to use. At each airdrome, the meteorological information received must be posted from hour to hour. The best means consists in having very legible conventional signs on a map, as is done at Le Bourget and in general at all the airdromes of the S. N. A. (Service de la Navigation Aérienne) in France. But this precaution does not suffice for utilizing the information as a whole. It is dangerous to rely on the memory of the pilots and errors of interpretation are to be feared.

It is necessary to place before the eyes of the pilot, on the aeroplane itself, a card showing graphically all the information in condensed form and indicating, by way of suggestion, the proper itinerary for him to follow and the altitude at which he should fly. It is also advisable to obtain from pilots their detailed criticism of the information furnished.

With the "Compagnie Franco-Roumaine" I use a graphic system which gives good results. Since the adoption of this system the pilots have gradually acquired greater confidence in the value of the reports, and furthermore, it is possible to keep strict watch over the work of the meteorological stations.

Communication from Ground to Aeroplane

In all of the above, we have supposed that the aeroplanes did not have radiotelegraph and radiophone apparatus enabling communications with the ground.

With the approaching use of very large aeroplanes, necessarily involving radio-electric installations, the meteorological communications will also be facilitated. There will also be an exchange of information between the ground and the aeroplane.

In general, an aviator should receive information from the ground regarding a region an hour before flying over said region (sounding by the central station). This information determines his average altitude of flight. He should also receive the reports from the auxiliary observation stations giving the visibility and the cloudiness, thus enabling the determnation of his itinerary.

This precaution is fundamentally important for the landing zone at the terminal. In fact, it must be ascertained whether the visibility is sufficient. The duty of the navigator aboard the aeroplane is to intetrpret this information and inform the pilots as to the proper route. Furthermore, instruments like the "navigraph" of Mr. Le Prieur, enable accurate checking up of the route followed. It also enables at any instant the determination of the air speed. We can therefore conceive of the possibility of accurate observations aboard such an aeroplane, which would constitute a veritable flying observatory. There will then be a means of checking ground observations on the aeroplane from which other aeroplanes flying over the course can profit greatly. This advantage, especially in foreign countries, will partially offset the lack of satisfactory ground meteorological service. The times for making the soundings must be determined by definite instructions. They must precede, at each point, the regular passage of the aeroplane by an hour. On the other hand, ground stations must always be ready to reply to questions from an aeroplane. The aviators must listen frequently for short periods, in order to allow the ground stations to send them particularly urgent information, especially storm warnings.

Such are the principles, learned by experience, which must guide us in the organization of a meteorological service.

(Translated by the Notional Advisory Committee for Aeronautics)

Texas College Students to Receive Flying Training

The Air Service Unit at the Agricultural and Mechanical College of Texas is the youngest of five units in that State, having been organized in December a year ago. The unit started this year with 102 men, but the 609 examination (physical examination for fliers) disqualified about forty of these men. The students are a highly enthusiastic bunch, all intensely interested in the course, and many of them will eventually become reserve pilots.

During the first two years at this college, students cover elementary military subjects. During the last two years they cover in the main purely Air Service subjects, including aeroplane engines, aeroplane instruments, bombing, aerial gunnery, aerial photography, radio, machine guns, artillery observation and Infantry and Cavalry liaison.

At the end of the Junior year, the students attend a six weeks' camp at some Air Service field, where they are given a great deal of back seat work as observer and also given an opportunity to take short courses in engines, aeroplanes and all other work connected with an Air Service station. Upon graduation these men are given commissions as reserve second lieutenants and ordered to active duty for a period of six months in order to permit them to obtain their flying training.

The camp this summer will be held at Kelly Field, and the Junior Class is hard at work preparing themselves for the work they will do at the camp this summer. Due to the hardships of the 609 examination, there will be only seventeen men qualified for the camp.

The Cadet Major of the Squadron, James E. Gardner, is a former Air Service officer, who left school during the war and enlisted for the Air Service. He completed his ground work course at the University of Texas, his primary training at Call Field, and his advanced training at Ellington Field. After the Armistice, Mr. Gardner returned to college, and will graduate this year in architectural engineering. He is considered one of the very best cadet officers at this institution, and it is in a great measure due to his earnest work for the squadron that such an esprit de corps in this unit has been built up so soon.

COMMUNICATIONS AND BEACONS ON AIR ROUTES

By CAPTAIN FRANCK

Service Technique de l'Aéronautique*

Need of Communications and Beacons

The aircraft which undertakes a journey requires information as much before its departure as during the flight. During travel it is necessary to find a route marked by some suitable system of beacons.

Communications.—The information required before departure is chiefly meteorological in nature. For the navigator starts only in case the weather announced to him along the route is such that he can safely undertake the journey with the aircraft and the navigation instruments at hand. Meteorological information consists in the knowledge of the existing weather conditions at different points along the line and in a forecast of the probable weather along the route during the trip. Now the weather can be known and the forecasts made and distributed only when a system of very rapid communication is satisfactorily organized.

When he has decided to start, the air navigator should notify the point of destination and the principal landing fields along the route. The latter would then be able to have the beacons in readiness, in case they are not constantly in operation, and to assist the aviator by all possible means during the trip. During the flight, incidents may occur (such as changes in the weather and difficulty in finding the way) which will make it necessary for the aviator to communicate with the ground. The ground organizations whose duty it is to look out for his safety may have information to send him (sudden and unforseen changes of the beacon storm warnings, etc.). Finally, on arriving at his destination, he must notify the aerodrome from whence he departed, as well as the intermediate landing fields, so that at any moment they will be posted as to the position of the different aircraft.

The system of comunications of air routes must therefore comprise comunications on the ground and between the ground and the aircraft in flight. These communications must be reliable and practically instantaneous. On this account it is necessary to employ means designed for this special purpose, to the exclusion of those used for other purposes. The latter means may however be utilized in case of failure of the former and such use should be anticipated and provided for in advance. It is no less true however that the airways need their own system of communications.

Marking.—Aerial navigation can use the methods of sea navigation and also similar instruments, compass and sextant, for example. But while the sea is practically motionless or influenced by regular currents, the air is disturbed by currents which vary almost constantly in speed and direction and which change with altitude. The result is that, when the aerial navigator no longer has a landmark to observe, it is impossible for him to take account of the possible changes in his drift and to follow precisely the desired route. It is therefore necessary to place more beacons along the routes he must follow. Lastly, it is necessary to give him numerous means for determining his position or for following a well-defined route without losing it, no matter what the weather may be.

Thus the marking of air routes requires day signals, night signals and electro-magnetic or other signals capable of replacing the visual signals in foggy weather.

Means Employed to Establish Communications and Beacons

a) *Communications.*—The only means of rapid communication suitable for aviation are radiotelegraphy and radiotelephony. In fact, these are the only possible means of communication between the ground and aircraft. On the ground, ordinary telegraphy or telephony could be employed, but their use would require the installation of special direct lines at a prohibitive cost. This method of communication would be of value only if multiple telegraphy and telephony made possible by the use of high frequency on ordinary lines, should become common and thus increase the efficiency of electrical circuits to the point of considerably diminishing the cost of a direct communication by wire. This point has not yet been reached. In France, the system of communication adopted on air routes is the following:

1. *Land Communications.*—These are maintained by the aid of continuous radio sets, with a range of 800 kilometers. These sets may be employed either for telegraphy or telephony, as desired. In practice, land communications are made by telegraphy, thus obtaining greater efficiency.

2. *Communications from the Ground to Aircraft.*—On the ground sets like those described above are employed. Messages transmitted by them can be received aboard aircraft up to 500 kilometers by telegraphy and by telephony.

On aircraft, the companies use the apparatus found in commerce. The range required depends on the distance between ground stations with which it is possible to communicate. The routes now in operation can work under favorable conditions with sets having a range of 300 kilometers.

Telephony is very practical for communicating between the ground and aeroplanes. In fact, it does not necessitate acqnaintance with the Morse alphabet. After a little training, any member of the crew can use, so that it is not necessary to have a radiotelegraph operator on board. On international lines, however, it is difficult for operators speaking different languages to understand each other by telephone.

3. *Organization of Communications.*—All the important landing fields and all of those where a meteorological station is installed are equipped with a station for land communication.

All terminal fields and all those where meteorological information is gathered are equipped with radio stations for communicating with aeroplanes.

On a given landing field which needs to communicate both with other fields and aircraft, these communications may be made either by means of a single station or two different stations, according to the volume of traffic.

b) *Beacons.*—1. *Day Beacons.*—These include route landmarks and markers on the landing fields.

To indicate the routes, the names of the landing fields along the way are marked with large letters. If this is insufficient the names of important places are marked either on the roofs or on the ground. Consideration has also been given to the question of beacons for air navigators in bad weather. For this purpose, captive balloons have been sent up above the layer of clouds during foggy or cloudy weather, but up to the present time this method has not given satisfactory results.

Landing fields are marked in the following manner. The center of each field is indicated by a circle with a diameter of 50 meters in which the name of the field is inscribed.

In certain cases, four lines radiating from the perimeter of the circle indicate the four cardinal points.

The boundaries of the landing field, wherever they are not evident, are marked by spaced lines on the ground, or by disks mounted on low supports. Special markers are placed at the corners of the landing field in order to outline its contour in snowy weather. All of the obstacles which may exist are indicated by red and white pennants.

The direction of the wind is given by a movable landing-T which automatically orients itself. A flag mounted on an elevated support indicates the direction which must be followed around the field.

2. *Night Beacons.*—The marking of routes is accomplished by the aid of special lights. The form of the beam is such that they are visible at an altitude of 2,000 meters and at a distance of 40 kilometers with medium visibility. These lights are located in the vicinity of landing fields which mark the route, to indicate their situation. If the number thus installed is insufficient, others are placed between the fields. They emit series of long and short flashes, in different and characteristic combinations.

The installation of very powerful lights at certain important points on air routes has been considered. Two are now being built by way of experiment. It is expected that they will be visible at a distance of 150 kilometers with a transparency of 9.925.

Landing fields are marked in the following manner: Their situation is determined as already mentioned for the marking of routes. Obstacles are indicated by different lights. The direction of rotation is given by a luminous circle; the direction of the wind by a series of lights on the same T used during the day.

The greatest difficulty at night consists in marking the place and direction for aircraft to land. The International Aerial Navigation Convention recommends a method which consists in dividing the landing field by means of lights into three sections: a landing section, a neutral section and a section for departure. But the direction of these sections must be changed whenever the wind changes. It would be necessary, in order to accomplish this, to have quite a large night personnel, or to adopt a system of subterranean electric lights placed under

NOTES ON PROPELLER DESIGN

The Energy Losses of the Propeller—I

By MAX M. MUNK

(Technical Note National Advisory Committee for Aeronautics)

THE knowledge of the different kinds of energy losses of the propeller and of the magnitude of the losses in each single case is of great value to the designer. There are three different kinds of energy losses, and the most important has been the least often discussed in the publications of recent years. This is the friction between the air and the blade when whirled through it. Suppose the propeller to be well shaped, so that each blade element is working under a proper angle of attack. Corresponding to the induced drag of an ordinary wing, there are then coming into action the slip stream loss and other similar losses to be discussed afterwards. Besides, there is the friction of the blade surface moved through the air.

The drag coefficient which expresses the relative magnitude of this friction depends, it is true, on the blade section and on its angle of attack or, what amounts to the same thing, on its momentary lift coefficient. But the variability of the drag coefficient for reasonable angles of attack is much smaller than often supposed, the variation for different sections as well as for different angles of attack being small. There is a certain minimum of the drag coefficient existing, which it seems can always be obtained under reasonable conditions by the proper choice of the section, whether the desired lift coefficient be smaller or greater. Hence it is admissible to assume the drag coefficient C_D to be constant for all propellers under those particular conditions for which it is chiefly designed.

The energy loss produced by the drag is the sum of all these losses of each single blade element. Let i be the number of blades, b their breadth at the point considered, v the velocity of the blade element relative to the air, r the distance from axis, dr the length of the blade element, and D the propeller diameter. The entire loss per unit time due to friction is then

$$i \int_O^{D/2} v(v^2\rho/2)\ b\ C_D\ dr$$

Excepting the velocity v all quantities occuring in this expression are only moderately variable and may be replaced by their mean values for the present purpose. This velocity determines the dynamical pressure $v^2\ \rho/2$, and this pressure is the sum of the dynamical pressure of the tangential velocity and of the velocity parallel to the direction of flight, for these two velocities are at right angles to each other and hence the sum of the squares equals the square of the resultant velocity. But the square of the velocity in the direction of flight is so much smaller than the square of the tangential velocity over the greatest part of the propeller blade that it is admissible to neglect it for the following estimation of the magnitude of the drag coefficient and to make a correction for it afterwards. Substitute, therefore, $v = 2\pi\ r\ n$ where n denotes the number of revolutions per second. The loss produced by the drag remains then

$$8\ \rho/2\ C_D\ b\ \pi^3\ n^3\ i \int_O^{D/2} r^3\ dr$$

This integral has the value

$$(1) \qquad \frac{1}{8}\ i\ C_D\ \frac{\rho}{2}\ b\ n^3\ D^4\ \pi^3.$$

The thrust calculated in the same way appears

$$(2) \qquad \frac{1}{6}\ i\ C_L\ \frac{\rho}{2}\ b\ n^2\ D^3\ \pi^2.$$

The lift coefficient C_L can assume very different values as it is not restricted by a lower limit as the drag coefficient is, and its upper limit is rather high. For several reasons, however, the lift coefficient actually used with propellers intended for similar conditions always keeps within narrow limits. A lift coefficient which is too small requires too large a blade area and hence too clumsy a propeller, also C_D/C_L is thus small as a consequence. A very high lift coefficient it not compatible with a small drag coefficient nor with a small ratio of the drag coefficient to the lift coefficient. There is finally the consideration of fairly good efficiency over a wider range of constant revolutions for different conditions of flight. For all these reasons the lift coefficient of propeller blades is far less variable than would appear at first glance, and this holds even more for the ratio

$$\frac{\text{lift coefficient}}{\text{drag coefficient}}.$$

This ratio has a maximum which occurs for moderately high lift coefficients, but the actual lift coefficient will not be very different from the most favorable one, and hence the ratio C_L/C_D can be assumed constant for a rough estimation.

This leads to a covenient approximate formula for the propeller loss due to friction. For the useful work per unit of time is T V, and hence the ratio of the loss of friction, as given in equation (1) to the useful work T V where the thrust T is given in equation (2) can be written

$$(3) \qquad A\ \frac{D\ n\ \pi}{V}$$

where A is a constant or at least is nearly constant for all good propellers under their best conditions of performance.

The approximation is valid only as long as the ratio of the tip velocity n D π to the velocity of flight is great and the efficiency is fairly high. If then the number of revolutions is prescribed, the consideration of the friction alone demands a small diameter. In intend to discuss the question of the best diameter more fully in a later note, but it may be mentioned here that for an usually small diameter the loss of friction ceases to be the dominant part of the entire loss and the second kind of losses becomes important, calling for a great diameter.

The losses of the second kind are the equivalents of kinetic energy transferred to the air in the form of regularly distributed motion. The chief part is the slip stream loss. It has been discussed so often during the past fifty years that it seems admissible to state the result without repetition of the proof. The ratio of the lost energy to the useful work performed by the propeller is *

$$\frac{1}{2}\left(\sqrt{1 + C_P} - 1\right)$$

where

$$C_P = \frac{T}{V^2 \frac{\rho}{2} D^2 \frac{\pi}{4}}$$

*N. A. C. A. Report No. 114 and Technische Berichte II, p. 78.

This becomes 1/4 CP for very small values of CP but the approximation is not good for greater values of CP where it gives values that are too great. This expression for the loss is the minimum occurring for uniform distribution of the thrust over the propeller disc. This condition is not compatible with a finite number of blades, for a blade like any other wing is unable to produce a finite density of lift at its utmost end. Hence the finite number of blades involves a small increase of the induced loss.

A third kind of induced losses is a consequence of the rotation around its axis which the slip stream assumes. This kinetic energy however is not entirely lost if the propeller is in front of the fuselage and of the wings. The wings produce a kind of honeycomb effect and straighten out part of the rotation. Besides, the decrease of pressure in front of the fuselage and the radiator diminishes the drag of the aeroplane.

The additional induced losses can be taken into consideration by introducing an effective diameter D′ smaller than the real diameter and using it for the calculation of the energy losses. If, for rough calculation, the approximate formula for the loss, 1/4 C_P, is taken, the result is too great, as said above, and it may be assumed that the additional losses are already contained in it.

The entire efficiency appears now

$$\eta = \frac{1}{1 + A\ D\ n\ \pi/V + \frac{1}{2}\left(\sqrt{1 + C_P} - 1\right)}$$

or approximately

$$1 - \eta \text{ is about } A\ D\ n\ \pi/V + B\ C_P$$

where A and B are constants which do not vary greatly for

Digitized by Google

different propellers under their most favorable conditions. A is expected to be about 3/4 C_D/C_L B to be in the neighborhood of 1/4 for great velocities of flight.

Another kind of loss is not considerable. This is the loss through the interference of the propeller and the aeroplane. This loss is not even necessarily positive. The interference in general creates a force between both propeller and aeroplane, increasing thrust and drag. This alone involves no loss. Furthermore, there is the increase of the drag of the fuselage by the slip stream. This is often added to the original drag of the aeroplane for matter of convenience, and not considered as a direct loss of the propeller, although it is to be attributed to its existence. The remaining loss of interference is small in general and can probably be neglected.

I have discussed the different kinds of energy losses of the propeller with the intention of determining the most probable value of the respective constants. The data available for this purpose are extremely scarce and unexact, but it seems pertinent and necessary to determine the most probable values and to use them until they can be replaced by some exact ones. The best method for obtaining these at present is the investigation of a stationary propeller of the same dimension and speed as an ordinary propeller, but especially designed for the test. These conditions were fulfilled to a certain extent in the tests of Dr. Schmid. * The scale of his propellers was large enough, but the speed was somewhat low. Besides, the sections investigated were comparatively poor, which is not surprising, for the tests were made as early as 1912. With one propeller, the distribution of velocity in front and behind the propeller was determined too.

This test showed that the slip stream loss was exactly 100% of the expected value. The loss due to rotation was confirmed to agree with theory to within 10% error, but here the exactness of the test was far less. This test then justifies the application of the theoretical coefficients for the determination of the induced losses,(leaving thee determination of the friction losses only to empirical investigation.

The same test of Dr. Schmid gives a lift coefficient $C_l = 0.50$ and a drag coefficient $C_D = 0.023$ calculated by means of the formulas 1 and 2. Thus C_l/C_D appears to be 22. This is in good agreement with the values known from the ordinary wind tunnel tests with wing models, if the induced drag is taken into proper consideration.

The second source of information is free flight tests which lead to the determination of the efficiency of the propeller. These tests consist in gliding tests with stopped engine, thus giving the drag of the aeroplane. This being known, flights with running engine give the propeller efficiency. With airships, the gliding is replaced by negative accelerated runs with stopped engine. The greatest error of the test comes in owing to the drag of the stopped propeller, which has to be subtracted from the drag obtained from gliding. I have previously published results of both kinds of free flight tests and refer to them, as I am better acquinted with them than with similar tests made by others. The tests with the Brandenburg seaplane gave a maximum efficiency of 71%, so did the tests with the Zeppelin airships. It has to be mentioned that both aircraft had a comparatively low speed and hence their slip stream loss was high. The method of calculation described in the first part of this note gave:

	C_L	C_D
Test of Dr. Schmid	.50	.023
Brandenburg Seaplane	.54	.024
Zeppelin Airships	.54	.025

From these data I conclude that the probable value of the minimum C_D for propeller blades is .024. As explained before, this coefficient refers to too small a dynamical pressure, the dynamical pressure of flight being neglected, and it should be applied when using the formulas 1 and 2 only. Now the mean tangential velocity is about

$$0.7\ \pi\ D\ n = 0.7 \qquad 10 \times 25\ \pi = 550 \text{ ft/sec.}$$

The velocity of flight is about 140 ft/sec, and the square of this velocity of flight is about 6½% of the square of the mean tangential velocity. The value for C_D appears from this to be 6½ too large. The most probable value of the drag coefficient is then finally

$$C_D = 0.020.$$

The presentation of this important value and of the reasons which lead me to its adoption is the main subject of this note. The value of C_L/C_D would appear to be 22. This value is not changed by the correction of the dynamic speed.

The constants are then expected to be A = 0.034 and B = 0.25. The maximum efficiency of any propeller is then about

$$1 - 0.034 \frac{D\ n\ \pi}{V} - 0.25 \frac{T}{V^2 \frac{\rho}{2} D^2 \frac{\pi}{4}}$$

For an average value of $C_L = 0.50$ this would give

$$1 - .034 \frac{D\ n\ \pi}{V} - .083 \frac{ib}{D\pi} \left(\frac{D\ n\ \pi}{V} \right)^2$$

An experimental method which also gives information on the air forces of propellers are tests with small propeller models, mostly at low speeds of revolution. These tests of course can not be used for the determination of the drag coefficient, as this coefficient depends on the Reynolds number. It has been found however that most of these tests give about the same result, so that if others give greatly different values, these tests must be considered as doubtful.

*Bendemann: Luftschrauben-Untersuchungen, Muenchen, 1918.

AVIATION IN MONTANA

Taking pride in the past advancement made in the face of unusual obstacles, Montana aviators are looking for this year to produce the greatest aerial activity yet known in this region. A number of new ships have come into the State, and various towns are preparing for the laying out of landing fields. In the past two seasons interest in flying has developed rapidly among the public, and the increase in civilian flying is expected to be rapid and large from this year on.

Although there was some flying in the State preceding the World War, the history of Montana aviation as a commercial proposition does not begin until the spring of 1919, when former Lieut. John Farrell organized the Montana Curtiss Aeroplane Co. at Bridger, Mont. The company operated two Curtiss JN4-D's successfully during the summer of 1919, but disorganized in the fall. The pilots were Farrell and W. G. Setzler.

The Inland Empire Aerial Training Corporation of Butte, was incorporated in the summer of 1919 and operated one Curtiss JN4-D. Former Lieut. L. G. Rees was the pilot. For a year the corporation was highly successful, adding two machines to its fleet, a Curtiss Oriole and another JN4-D. These machines were flown by former Lieut's R. N. Wilford and William Iverson.

Pilot L. G. Rees holds three records for flying in Montana. He crossed the continental divide with passengers in a Curtiss JN4-D five times without accident, flying at an altitude of 9,000 ft. He carried the youngest passenger ever taken aloft in Montana, Evelyn Schmidt of Whitehall, age ten weeks. This may be a world's record. Pilot Rees made the first regular delivery of newspapers by aeroplane in the northwest, carrying editions of the Billings Gazette of Billings, to Roundup and Winnett. In the summer of 1920 this company met a serious setback the Oriole being destroyed by fire.

Thereafter L. W. Lamb with Pilot Rees formed the Montana Standard Aeroplane Co. of Billings and operated successfully during the 1921 season. The company is now mapping out a large program for 1922. This company last year used Lincoln Standard Aeroplanes.

The Aero-Miles City Club of Miles City was organized in the winter of 1920-21. The Club flew two Curtiss Standards and accomplished much good work last summer. E. T. Vance and A. W. Stevenson were the pilots.

So far the various Montana aviation companies have derived their revenue from passenger carrying, exhibitions and different forms of aerial advertising.

Among the private owners of aeroplanes in the State are the following:

Perry J. Moore Jr. of Twodot, a rancher who has done considerable flying in Montana and California. He has a Curtiss Jennie.

Ex-Lieut. Seamore Anderson of Billings, who has made several long cross-country flights in his Curtiss JN4-D, and who recently was elected, Yellowstone County's chairman of the World Board of Aeronautical Commissioners.

Dr. Anderson of Roundup, who bought a K6 Standard in order to be able to answer country calls in a hurry.

Ed. Follensby of Helena, a garage man who is a flying enthusiast, and who bought a Canadian Curtiss for sport purposes.

Fletcher Woolston of Forsyth, who also owns a Canadian Curtiss with which he has done considerable flying throughout the State.

Ed. and Bob Westover of Billings, who purchased a Lincoln Standard Turnabout from the Montana Standard Aeroplane Co. and are doing good work in promoting civilian flying.

Mr. Hoil of Winnett, a banker who wanted fast transportation to and from the Cat Creek Oil fields, so he bought an OXX6 Standard.

The Montana Standard Aeroplane Company of Billings, is in position to furnish any information desired to pilots contemplating a flight into or through Montana this year, and will gladly extend it on request.

Where Wright Aeronautical Engines Are Made

ACREAGE Approximately 7 acres, located on Main Line of Erie Railroad.

AREA 90,000 square feet.

DESCRIPTION Four floors, size 75 ft. by 300 ft. Concrete and steel heavy mill type construction, 250 pounds per square foot loading.

EQUIPMENT The plant is equipped at present to produce, and is producing approximately 300 engines per year, with spare parts therefor, and has ample capacity in addition to provide adequately for all spare part requirements for all types of engines previously produced. The equipment of the plant provides for the complete manufacture of various type engines produced, including bronze and aluminum castings, except bar steel and drop forgings. The capacity of the present plant could be expanded to produce engines at the rate of five per day in the present building. In an emergency the present acreage would allow of enough additional buildings and equipment being provided within six to eight months to produce engines of any one type in quantities of at least 25 per day.

The plant has employed during the past year an average of 450 people, which includes a complete Engineering Department and Experimental Shop.

NAVAL and MILITARY AERONAUTICS

Joint Training of Coast Artillery and Air Service

The War Department is taking action to insure co-ordination of the Coast Artillery and the Air Service in coast defense, under the basic principles of warfare and training recently laid down. The chiefs of the two combatant arms concerned have been instructed to consider together the question of joint training, with a view to carrying out experiments in joint training and tests of material during the coming summer.

The war with Germany furnished such an exhaustive test of the powers of mobile troops that the doctrines of training for such troops were firmly established. Coast defense, however, was not so extensively tested, and many questions of the best methods and material to be used were not solved in battle. Since the war various experiments, such as the bombing of warships, have indicated the increasing power of aircraft in coast defense. It is with a view to developing the potentialities of this new arm, as well as to insure properly co-ordinated training, that the War Department is taking action.

Both branches undoubtedly have an important role in coast defense, and tests will be for the purpose of obtaining coordination in their training. It is expected these tests will include:

(a) Anti-aircraft target practice against air targets to determine the vertical range at which bombing planes could operate without being subjected to effective fire.

(b) Bombing practice against coast defense installations.

Scott Field is Working on Two Racing Balloons

Scott Field is constructing a second balloon for competition in the U. S. balloon race which is to be held in Milwaukee, Wis., next month. The race was to have been started at Milwaukee on May 8 and the local aviation camp was to have been represented by one balloon. With the changing of the date from May 8 to May 31, permission was given to A. Leo Stevens, the civilian aeronautical officer at the field, to construct a second balloon.

The first balloon is nearing completion and the second, which will be a sister ship, has been started. The ships will be known as U. S. No. 2 and U. S. No. 3.

Each of the balloons will have a capacity of 80,050 cubic feet and will be 105 feet from bottom of basket to top of the balloon. Word of the changing of the date for the starting of the balloon race has just reached Mr. Stevens from the Aero Club of New York.

The balloons which will be entered in this year's race from Scott Field will be the second and third ships ever entered in a race. Mr. Stevens who is supervising the construction of the two ships at Scott Field also directed the manufacture of the first ship which was entered in the race at Omaha, Neb.

A large crew of men are busily engaged on the balloons at Scott Field.

The 318th Pursuit Group, Organized Reserves

The 318th Group, Pursuit, Organized Reserves, with headquarters in Indianapolis, has three squadrons, the 462nd, 463rd and 464th in Indiana (Kokomo, Wabash and Indianapolis) and the fourth, the 465th, at Louisville, Kentucky. At present there is only one Regular Army Air Service officer detailed with the Group.

The 464th Squadron at Indianapolis is the only organization nearly approaching its full complement of officers. Some enlisted men have already been signed up by recruiting officers appointed within this squadron, and all details pertaining to the squadron are being studied and rapidly mastered by the flight officers in order that the unit may begin to function as such. The remaining squadrons in Indiana have only enough officers assigned, or available for assignment, to compose a full flight in each.

The former Air Service officer presents a different problem, regarding applications for Reserve Commissions, from a line officer. The reserve line units have a more or less full quota of officers, whereas the Air Service units are sadly lacking in the available number of commissioned personnel. Being a comparatively new branch, there are no officers of long experience such as may be found in the Infantry, for instance. There are very few men holding Reserve commissions in the grade of captain, and hardly any in the field officer grade.

The work of an Air Service officer is considered very hazardous by wives and families of ex-aviators, most of whom have acquired the first named since leaving the service, so that pressure is brought to bear upon those men who would like to try their "hand" again by entering the A. S. R. C.

The majority of men now holding reserve commissions are those who completed their training just before the armistice or remained in long enough to get the rating. The old flyers look askance at the Reserve program, that is, those who have remained in touch with Acts of Congress regarding the Reserve Corps. Once a flyer, there will always be an attraction for them in flying. So to induce these valuable men to re-enter the game as an officer in the reserves, they must have a definite assurance of a sufficient amount of flying. With this assurance, it is believed there will be applications and enough men commissioned to fill the quotas desired.

The Aero Club of Indianapolis, most members of which are numbered among the personnel of the 464th Squadron, are endeavoring to acquaint all former service men, by personal contact and publicity gained in their activities, of the fact that the 464th is going to fly—and very shortly. The dedication of Schoen Field on Sunday, March 26th, was attended by all members of the organization. Schoen Field, at Fort Benjamin Harrison, is named in honor of an Indianapolis boy who was shot down overseas. This dedication marked the first official appearance of the 464th.

One steel hangar is being erected at the field, and material for two more will arrive shortly. There will be about ten JN6H planes, one DH4B, and probably a Fokker, for use by the squadron this spring and summer. This should increase the enthusiasm and esprit not to say applications for Reserve Commissions.

Death of Major Simons and Lieut. Fitzpatrick

Two Army Air Service pilots made the supreme sacrifice in order to advance the science of aviation—Major John W. Simons, Jr., and 1st Lieut. Gerald H. Fitzpatrick, who were instantly killed near Ellington Field on April 3rd, when the planes they were piloting collided in the air.

Major Simons, who was 35 years of age, had 14 years' service in the Regular Army, being appointed a 2nd Lieutenant in the Infantry on January 4, 1908. On March 3, 1914, he was promoted to the grade of 1st Lieutenant. During the World War he was detailed a Captain in the Aviation Section, Signal Corps, in November, 1917, and he was promoted to the grade of Major on February 23, 1918.

He was sent to Rockwell Field, San Diego, Calif., for flying training, in April, 1918, and completed same on July 15, 1918, when he was rated as a Junior Military Aviator. From Rockwell Field he was sent to Langley Field, Hampton, Va., as a representative of the Bureau of Aircraft Production in command of all aircraft experimental activities at that station. His next assignment was that of Commanding Officer of Park Field, to which station he was sent in November, 1918, remaining there until September 18, 1919, when he was assigned to duty as District Material Disposal and Salvage Officer at Buffalo, N. Y.

In August, 1920, he was transferred to the Office of the Chief of Air Service, Washington, D. C., for duty as Assistant Adiministrative Executive. Desiring to receive further flying training, his application to take the advanced course in pursuit training at Ellington Field was approved, and he proceeded to that station in January, 1922.

Major Simons was considered an excellent pilot, and made many long cross country flights. Of a genial disposition, he was well liked by all who came in contact with him, and his many friends in Washington and elsewhere will keenly feel his loss.

Lieutenant Fitzpatrick was 24 years of age and a native of St. Louis, Mo. He was appointed a flying cadet in October, 1920; and was sent to March Field, Riverside, Calif., for flying training. He completed his primary training in April, 1921, took the examination for a commission in the Air Service, Regular Army, and received an appointment as 2nd Lieutenant on August 4, 1921, being shortly thereafter promoted to 1st Lieutenant. In December, 1921, he was sent to Ellington Field for advanced training in pursuit flying.

The Air Service sends its condolences to the bereaved relatives of these two officers.

FOREIGN NEWS

London-Brussels Service

The Instone Air Line, Ltd., has now been approved by the British Air Ministry as the company to operate a subsidized air service between London and Brussels.

Night Flight Croydon to Lympne

The first flight by night over the British portion of the Continental Air Route (Paris, Brussels, Amsterdam, etc.), was carried out by an Air Ministry machine in order to test the ground organization which has been established for commercial flying by night between London and the Continental capitals.

The aeroplane which carried eight people, including a navigator, wireless officer, and the Air Ministry officials responsible for the lighting and wireless arrangements of the route, left Biggin Hill about 8:30 p. m., flew to the London Terminal Aerodrome, Croydon, and landed there. The Pilot in charge, who has had great experience, expressed the view that the flood lighting arrangements on the aerodrome, by means of dispersed searchlight beams, together with the illuminated Landing "L's", were the best he had seen and made landing as easy by night as by day.

The aircraft left Croydon Aerodrome about 9:20 p. m. and steered a direct course for Lympne Aerodrome on the coast. Temporary Aerial Lighthouses were in action at Tatsfield and at Cranbrook, and these were easily picked up. Shortly after passing the Cranbrook Light the Pilotage Light on Lympne Aerodrome became clearly visible. The machine then flew over Lympne Aerodrome and continued over the Channel towards St. Inglevert, the first aerodrome on the French side. The Marine Lighthouse at Cap Gris Nez, which had been visible as soon as the aircraft was over Biggin Hill, gave an excellent leading mark and very soon the French Aerial Lighthouse on St. Inglevert Aerodrome also came in sight. Turning back on its course the Aeroplane then crossed the coast near Folkestone and headed direct for the Pilotage Light at Lympne at which aerodrome an easy and smooth landing was effected. Leaving this station at about 11:30 p. m. a course was re-traced to Croydon, the lights of the Terminal Aerodrome being easily picked out from all the mass of lights of Croydon and London generally. After circling Croydon Aerodrome the aircraft was headed for Biggin Hill where a landing was effected with the help of wing tip flares and ground flares.

The general impressions of those who made the flight were that it is easier to find a course by night than by day and that provided the Continental ground organization is as good as our own there should be no difficulty whatever in commercial night flying over the London-Paris route.

F. Handley Page States German "Gotha" Was Copy

London—The Handley Page Co. has a claim before the Commissioners on Inventors' Awards concerning the "O" and "V" type of biplane as made by others during the war, by direction of the wartime authorities.

F. Handley Page, managing director of the company, testified in connection with the claim that the German "Gotha" was a copy of his machine and until the Germans captured a Handley Page, all complete, and were able to fly with it, they were not conversant with the structural details or convinced of the aerial dynamics in regard to big machines.

Austria: Conditions Governing Flight

In consequence of the admission of Austria into the League of Nations the provisions of the Treaty of St. Germainen-Laye relating to Allied aircraft flying over Austrian territory are no longer in force.

Foreign aircraft flying over or landing on Austrian territory must be provided with a permit issued by the Austrian Ministry of Roads and Communications.

China's Air Service Wilting

Chinese "finance" was ever a thing to be marvelled at, and one of the latest enterprises to suffer at its hands appears to be the Air Service which was inaugurated last year under such favorable auspices with the assistance of Messrs. Vickers, Ltd. It seems that the cash provided, which should have gone to run the service to a commercial success, has filtered away through the Government inaptitude until nothing remains for wages, coupon interest, or anything else —without some financial miracle happens. From latest reports it looks as if the whole scheme may easily become another monument to Chinese methods of how not to do it.

London Continental Air Service

According to London newspapers, thirty new air expresses are to be "put on" the London Continental Air Service this year to cope with the great increase of traffic. The British contribution includes a number of an improved type of twin-engined Handley Page machines, each for 12 passengers. In addition, there will be a fleet of machines built by the DeHaviland Aircraft Company.

A new fleet of 14-seater Goliath airplanes will be operated by a Belgian company between London and Brussels, while a week or so hence will witness the trials of the first of a fleet of four-engined 25-seater super air expresses that one of the French companies is building. The airways are also to be extended, and instead of Paris being the terminus, it will become a junction, with services running to Marseilles, Lausanne, Warsaw and Casablanca, in Northern Africa, while it is hoped to extend the airway on the British side from London to Manchester and then across to Dublin.

Russo-German Air Traffic Company

A statement in a Russian newspaper announces the formation of a Russo-German air traffic company, which will begin operations by establishing an air route between Moscow and Konigsberg, to connect with the Berlin-Konigsberg express train services. An agreement has already been concluded between the Russian commercial delegation in Berlin and German interests, among whom are Herr Rathenau's organization, the General Electric Company, the Hamburg-Amerika Line, and the Zeppelin Company. Germany is to recover full freedom in the matter of the construction of non-military aircraft, and the establishment of air services beginning in May.

Mexican Air Service

Trade Commissioner P. L. Bell, at Mexico City, has sent to the Automotive Division, Department of Commerce, a translation of a permit recently conceded by the Mexican Ministry of Communications and Public Works to the representative of the Cia. Mexicana de Transportes Aerea, S. A., for the establishment of an airplane service between Mexico City and points in the States of Vera Cruz and Tamaulipas. In view of similar permits ready to be granted in the near future, this one may be taken as a very good example of what parties interested in the development of commercial aviation in Mexico may expect in the way of Government permits and their conditions. It should be noted, furthermore, that this permit is not an exclusive one and does not carry the usual features of the old-time "concession."

Netherlands Market

Mr. Joseph W. Vander Laan, Secretary to American Legation, The Hague, reports that the market for American aircraft in the Netherlands is centered in the Army, the Navy and the Colonial aviation, and in the Royal Dutch Air Service Co., known abroad as the K. L. M. While the needs of the Dutch Army aviation are relatively small, and the K. L. M. has definitely decided that during 1922 it will fly Fokkers, American aircraft builders may be able to compete successfully for contracts from the Navy and the Colonial aviation.

Czechoslovakia

Engineer Janak, head of the Automobile and Flying Department of the Ministry of Social Welfare, returned from Berlin on February 17th. He concluded with representatives of the German Government a provisional agreement on a reciprocal basis regarding regular air service, passengers and goods, between Prague and Berlin. The agreement, it is said, will be signed in March. The governments of the two countries will each select a company to participate in the service, which will either be alternatively or simultaneously in opposite directions.

This means that as soon as Germany is permitted, by the Peace Treaty, to make international flights (end of 1922) German machines will be allowed to fly to Prague and over Czechoslovak territory. A new flying company will be formed at Prague, under the protection of the Legio Bank, with a capital of 8 million kronen. Deputy Rychtera will be president of this company. The amount of the government subsidy, which will be paid to this company, has not been fixed, but it is expected that it will be equal to that allotted the Franco-Roumanian Company.

This new Czechoslovak aviation company will use, as far as possible, aeroplanes of Czech manufacture. Recently the "Aero" Aircraft Factory at Prague has successfully tried out an air transport limousine, which will probably be purchased by the new aviation company. The "Aero" limousine has a wing area of 52 sq. meters and a carrying power of 40 kilos per sq. meter, weight 1300 kilos, and will have a capacity of 5 persons and 100 kilos of baggage, and will carry petrol for four hours' flight. The engine is a German 260 h. p. Maybach motor. The Military Aircraft Works are also working on an air transport limousine designed by engineer Smolik.

Prague-Vienna Service

It is reliably reported that negotiations have begun between representatives of the Czechoslovak and Austrian Governments regarding a regular air service between Prague and Vienna.

Buenos Aires-Montevideo Service

The first trip of the new bi-weekly aeroplane service between Buenos Aires and Montevideo took place on December 17th, the distance of 220 kilometers across the River Plate being covered in approximately 1 hour and 10 minutes. The aeroplane has room for four passengers. On the first return trip 1,270 letters were carried to Buenos Aires.

A very successful aviation meet was recently held in Montevideo. Two Avroa, two Spada, and a Salmson were piloted by daring aviators, who thrilled the audience by corkscrew and Immelmann turns, the "falling leaf," and "looping the loop."

Honduras School

The Young Men's Club, which is interested in the advance of aviation in the country, is about to order aeroplanes from Italy for the equipment of the first Honduran School of Aviation.

Bristol Engines in France

We understand that the Bristol Aeroplane Co., Ltd., have concluded arrangements for granting the sole license to manufacture the 400 H.P. "Bristol" Jupiter radial air-cooled aero engine in France to the well-known Gnome & Le Rhone Engine Co. The announcement is of more than ordinary interest from the fact that this is probably the first occasion upon which the manufacturing license for an aero engine of British design has been acquired by a French manufacturer and is an indication of the high estimate formed in regard to the "Bristol" engines by the French aviation experts. The fact that the "Bristol" Jupiter and "Bristol" Lucifer engines are the only two air-cooled engines which have ever satisfied the strenuous conditions of the British Air Ministry Type Tests, coupled with their excellent record for reliability and performance in the air, has created a great impression in Continental aviation centers. The selling rights for the "Bristol" Jupiter engine in France and many of the countries of Europe have also been ceded to the Gnome & Le Rhone Co.

Planes Assist Seal Catching

A Grand catch of 50,000 seals is recorded from Montreal as the first week's haul of the Newfoundland Sealing Fleet, which was guided by aeroplanes to the location of the herds.

France to Have a 1922 Aero Salon

It has now been definitely decided by the Chambre Syndicale des Industries Aéronautiques that they will hold an Aero Exhibition in Paris this year. It will be, as before, at the Grand Palais, and although the actual date is not yet settled, it will probably be in December for a fortnight, although there are many who would prefer September to be the selected month.

SOARING FLIGHT

A Study of the Vulture and Golden Eagle

(*Continued from page 7*)

THE Eagle fears none but man, and even him he fears but little. Brought to bay, he does not hesitate to hurl himself at his enemy. In captivity he is at first exceedingly dangerous, and his ferocious temper renders him an untamable animal. It requires great skill to succeed in impressing him with fear, and when he becomes excited he will fight to the death.

Nature has created him to keep down undue increase. In this he is like the tigers, the sharks and the pike. This tyrant of the air is abundantly provided with all the weapons necessary for his murderous life. His arms consist of eight talons as long as a finger, curved and sharp-pointed and moved by terrible muscles. His much-hooked beak serves him to carve the animal perforated by his talons.

His wings are large and exceedingly strong. They are preeminently adapted to sailing flight. He rarely beats the air unless there is no wind, or unless he is loaded with a prey. Pen is powerless to depict the majesty of his gait, the amplitude of the immense circles which he sweeps in the air. At times he is absolutely motionless. He is examining the field or watching a prey; then suddenly he drops hundreds of yards. He falls like a meteor with the velocity of bodies falling through space.

The speed is such that it produces a sound difficult to describe. It is not like that of a bullet or of a cannon ball, but must be heard to get a true conception. Then, when within a dozen feet of earth, his wings' great strength safely checks his descent; and this at once, in half a second—merely by expanding his wings to their full spread.

His skill is wonderful; never a miss makes he. His eyes are excellent. From high up in the air he spies out the rabbit hiding in the thicket, or the inconspicuous duck swimming among the reeds. He uses his talons, the arms with which he kills, in a remarkably efficient manner. In captivity, when he is hungry, with a single claw he catches on the fly the morsels of meat thrown to him, and never misses them if they pass within his reach.

His movements have all the precision of those of small birds. He is free, quick, sharp, and powerful in his movements. Above all, his power of taking in all at a glance is very remarkable. As the motor-muscles of the eyeball are but little developed, he is compelled to turn his head whenever he desires to see anything sharply. His head then assumes splendid poses. His eye, that brilliant gem set under a deep arch, darts out lightning glances. His curved beak, his savage air, his sharp head-feathers, bristling up and forming a diadem—all that ensemble of vehement sweeping outline—make the Eagle a model of audacity and of power.

He lords it over a territory which he always selects of vast extent. All the smaller mammals dread him; the young of larger animals fear to be seen by him; the young chamois crouches up to its dam, the old bucks call the herd and stamp their feet with fury. Man himself, in infancy, has been attacked by him.

He is intelligent only from a hunting point of view. A very interesting spectacle is that of a family of Eagles making a raid in order to furnish the nest with provisions. The male is up a hundred yards in the air, quite motionless. The female is beating the thickets. Her flight while doing this has an ease of great elegance. She follows the undulations of the ground without effort, glides from one hill to another, descends and reascends the mountain slope. When a prey appears the two spouses are upon it at the same time. It often happens that a hare starting up 10 yards from the female is caught by the male, who was stationed a hundred yards away in the air. He dives head-formost, is upon the prey in four or five seconds, picking it up on the fly. If she is in the mountains, he first plunges into the valley with his load, and with great wing beats reascends to his eyrie. There the spoils are divided, and this never takes place without much dispute, despite the matrimonial bonds.

Hannover Glider Won Highest Awards

Mr. George Madelung, now connected with the Glenn L. Martin Company, Cleveland, Ohio, took part in the management and was in the Rhoen during the soaring competition held in Germany last year. In view of the statements published in AERIAL AGE crediting the highest awards to the Aachen Soaring Monoplane, Mr. Madelung points out that a glider designed by him, the Hannover, won the highest awards, which were 60 per cent more than those won by the Aachen.

As to the record breaking flight of Mr. Klemperer, which took place on August 30, 1921, this record was exceeded on September 5 by the Hannover glider which made a flight of 15 minutes 40 seconds in which it covered a straight line distance between starting and landing points of 4⅗ miles.

Wing Areas and Weights of Soaring Animals

Perhaps the heaviest of the soaring fliers is the California Vulture which often weighs as much as twenty pounds. Turkeys often weigh twice this, while the albatross is occasionally found weighing eighteen pounds. Still heavier than these may have been the Petrodactyl (now extinct) which, however, weighed no more than thirty pounds.

No flying creature that ever existed appears to have been as heavy as the combination of a man with the lightest structure that can be made to support him, and this fact often has been cited as an argument against the possibility of human flight. But in this connection it is a significant fact that the areas and the power required to support a given weight steadily decrease in passing from the smaller flying animals to the larger.

The most conspicuous features to be discerned in a study of soaring bird forms are the usually extreme length and narrowness of the wings, the lower sustention per unit of area than prevails with flapping fliers and a quite different type of curvature to the wing sections.

The pterodactyl, a bird-like reptile, which is known only from the discovery of fossil remains in strata of the Cretaceous period, measures in ordinary specimens about twenty feet from tip to tip. They were, however, very light, the wing bones that have been found being mere shell-like tubes of large diameter and extreme thinness. (The fact that there once existed a larger flying animal than any existing today has been held to prove a greater density to the earth's atmosphere in pre-historic times.) Calculations of the power exerted by this reptile in flight show that it required .036 horsepower. Its weight being thirty pounds and wing area twenty-five pounds, its weight is only 1.2 pounds per sq. ft. and 833 pounds per horsepower.

Table of Soaring Animals

Name	*Weight (pounds)*	*Wing Area (sq. ft.)*	*Pounds per sq. ft.*
Cabbage Butterfly	.000169	.00942	.0179
Maiden Dragon Fly	.000423	.01415	.0298
Laughing Gull	—	—	.62
Sparrow Hawk	.549	.69	.79
Herring Gull	2.18	2.41	.9
Stork	4.78	4.57	1.04
Scavenger Vulture	—	—	1.052
Turkey Buzzard	—	—	1.052
White Pelican	—	—	1.052
Pterodactyl	30.	25.	1.2
Sea Eagle	10.57	8.05	1.30
Griffon Vulture	—	—	1.456
Eared Vulture	—	—	1.456
Condor	17.	9.85	1.726
Flying Fox	2.91	1.65	1.76
Flamingo	—	—	1.818
Albatross	25.36	8.12	3.12

RADIO DIGEST

Radio Equipped Planes

Spokane, Wash.—Radio equipment is to be installed at once in aeroplanes of the United States Aircraft corporation here, acording to announcement by C. H. Messer, president.

With the equipment, capable of sending or receiving messages for 1,000 miles, the ships can be at all times in touch with the field. Receiving equipment will consist of wireless telephones. Additional safety in operation and greater usefulness will result from the installation of the phones, Mr. Messer said.

All pilots and students of the company must learn radio as a part of their course, according to Mr. Messer, inasmuch as he considers it one of the big steps in the advancement of aviation.

"By means of the wireless we will at all times be in touch with the local field," Mr. Messer said. "It will be impossible to lose the way or the sense of direction in fog or heavy smoke from forest fires.

"As soon as we have the equipment installed and under way, we will invite the public to the field to witness the demonstration of the men in the ship at a distance talking to persons on the ground.

"In addition we plan to put a receiving set in an automobile and go to all larger cities of this district and give demonstrations.

"Instruction work of a preliminary nature will be given at our Modern Auto school, but later pilots and students will be given their work in the air while actually flying.

"By means of equipment we are planning to install at the field, a device known as the 'radio compass.' It is so worked that a pilot, no matter what distance he is flying, can locate his own field and tell the exact direction in which he is traveling. The equipment we will use has been given an initial tryout."

Congress to Rush Bill for Control of Radio

Congress will expedite legislation vesting control of radio communication in a general advisory board under the Department of Commerce, it was declared, following conferences of Secretary Hoover and Congressional leaders.

Senator Kellogg (Minn.) and Representative White (Me.) will have charge of the radio bill now being drafted under Mr. Hoover's direction by a committee of experts.

Mr. Hoover's reports today showed that radio users are increasing at a tremendous rate and that applications of amateurs continue to pour into the Department of Commerce asking for licenses to set up transmitting stations.

Health Hints by Radio

A semi-weekly "radio telephone health bulletin service" has been inaugurated by the United States Public Health Service. It is planned to broadcast every Tuesday and Friday through the naval radio station at Anacostia, Va., a message of advice or how the average man and woman may insure continued good health. Under very favorable weather conditions it is expected that the messages will be heard on the Pacific Coast, in Europe, and the north parts of South America.

Radio Telephone Broadcasting in France

The popularity of radio broadcasting has extended far beyond our own borders. England is doing a little radio telephone broadcasting, so is Berlin, and the idea is taking real shape in France. We learn from a recent news dispatch that 20 ballet girls danced to music played 25 miles away, as a feature of a matinee. The performance was witnessed by Prof. Branley, the pioneer wireless worker, and ex-President Poincare.

Guiding Radio Waves

A Ukranian engineer is reported to have discovered a method by which radio messages may be sent to a definite receiving station without the danger of being intercepted by other stations. It is stated that by means of a simple apparatus the so-called "locker power line" of the magnetic field may be straightened out and grouped into parallel rays. These rays are said to do away with the necessity of aerials. If this report is true, it seems that we are on the verge of a new epoch in radio. However, we shall have to wait for complete details before passing judgment on the merits of this new invention.

Medical Servico via Radio

Arrangements have now been made whereby any ship provided with a radio outfit can receive prompt medical service from the United States Health Service, through one of several Radio Corporation of America stations and other stations. When it is remembered that only a small proportion of the total number of ships equipped with radio have a ship doctor, the value of medical service via radio becomes apparent. The ship in need of medical service can now call up the nearest radio station, state the nature of the case or cases requiring medical attention, and receive a diagnosis of each case and complete instructions as to treatment within a few minutes.

High-Power Vacuum Tubes

In connection with Great Britain's Imperial Chain—a world-wide radio system that has been under way for a long time—the Technical Committee recommended the use of high-powered tube installations. A considerable amount of very valuable work has been carried out in the past year by the British Admiralty, working in conjunction with the Mullard tube builders. Much progress has been made in the construction of silica tubes, which have now been made in 10-kilowatt sizes. The result of this work will undoubtedly be seen in the forthcoming year. We may expect a large number of land stations operating on valves of large power.

Crystal Acts as Valve in Receivor

The simplest radio receiving set, states Jack Binns, in the N. Y. *Tribune*, is the crystal detector, capable of receiving music and speech for a distance of twenty-five miles under practically all conditions and wireless telegraph code over very great distances.

In previous articles on this page I have described aerials of various types, protective devices for them, and the manner in which electro-magnetic waves are produced and propagated through the ether. In this article I propose to give a description of the action of the crystal detector in the receiving set.

In the first place there are a number of ways in which the crystal detector can be used: the simplest is by placing it in series with the aerial and the ground, with the telephone receivers shunted across it. This is a very unsatisfactory method, because it does not permit one to tune out any unwanted signals, and the consequence is that a great deal of interference is obtained.

The remaining methods of utilizing the crystal can be roughly summarized under the general heading of "tuning apparatus." This may consist of what is called a "single circuit" or a "double circuit," the latter being the best of all. The single circuit may consist of a tuning coil, with one or two sliders, or a variometer, or a honeycomb coil. In the latter case a condenser in series is required in order to obtain tuning. A double circuit may consist of a loose coupler or a vario-coupler.

Now, this tuning apparatus is required in order to put the entire receiving equipment into electrical resonance with the incoming wave. This can best be illustrated by using the analogy of two tuning forks. If you get two tuning forks of exactly the same pitch and place them at different ends of a room and then strike one, the other will vibrate in unison with it. If, however, you take a tuning fork which has a higher or lower pitch it will not respond in any way to the vibrations of the other. This is exactly what happens in the tuning circuit, and the adjustments that you make put that circuit into the same "pitch" or resonance as that of the incoming wave from the broadcasting station.

It can be readily seen, therefore, that with a single circuit, which must necessarily include the aerial, as close tuning cannot be obtained as with a double circuit, for this reason: the aerial receives all waves that pass over it and the current received is passed to the ground. Those currents that are in syntony with the aerial circuit will be recorded through the detector in the telephones. Of course, it is impossible to get 100 per cent efficiency in such tuning, and some of the undesired waves passing over the aerial will be recorded also, despite the fact that they are not of the same wave length as that to which the aerial circuit is attuned.

A double circuit means the addition of a secondary oscillating circuit. In the case of a loose coupler, this means the secondary inductance and a variable condenser shunted across it. The secondary circuit is put into resonance with the primary or aerial circuit bv adjusting the number of turns in the inductance and the amount of caoacity in the condenser.

It will thus be seen that while the aerial circuit may respond to some of the nnwanted waves, the chances of the secondary doing so will be very remote. By varying the coupling between the primary and the secondary, these unwanted signals are still further eliminated. Similar action takes place in a vario-coupler.

This is the condition that we are now confronted with, so far as the oscillating circuits are concerned. The next job for

Digitized by Google

the receiving instrument is to record the waves that have been received. As these waves have a frequency of 830,000 cycles per second, in the case of the broadcasting stations using a 360-meter wave, it will readily be seen that they are far too high for the telephone receivers to respond to, and, moreover, they consist of alternating current. The problem is to reduce this so that the telephones can respond and reproduce vibrations within the range of human hearing.

This is the job that the crystal detector has to do, and the most sensitive of all forms of crystals used for this purpose is galena, which is a sulphide of lead found in large quantities in the Middle Western States. Galena has the peculiar property of permitting a current of electricity to flow through it in one direction only. It completely checks current flowing in the opposite direction. In other words, it acts in the electrical circuit just in the same manner as the valve does in a water pipe system. The valve permits the water to flow freely in the direction that it is desired to have the water go, but if by any chance or circumstnce there should be a back flow of water the valve immediately closes and stops the back flow from going any further. Galena does the same thing in the electrical circuit.

We have now got the condition where the high frequency alternating radio currents are literally chopped in two by the detector and only half of them permitted to flow through the telephones. We have, therefore, a pulsating instead of an alternating current, and the pulsating current is flowing in one direction only. The groups of pulsations act together and cause the telephone transformer to reproduce sounds that are audible to the ear, and it is in this way that we get a reproduction of music and voice.

I have often been asked why it is that a crystal detector will receive wireless telegraph signals over very great distances, but yet is reliable so far as music and speech are concerned only over distances of approximately twenty-five miles. The answer to this question is not so difficult as it would seem. When we are dealing with telegraph code we have a current of constant amplitude sending out the dots and dashes. In other words, the "tone" or "pitch" of the signal never varies. In the case of the voice or the music we are not only dealing with varying amplitudes of sound, but we are also dealing with loud and soft inflections.

Lightning Danger to Antenna Small

If your radio installation is not already installed according to regulations you should attend to the matter at once, says G. K. Thompson radio superintendent of the Amrad Co., in the New York *Herald*. The regulations are in force the year round and should be complied with as far as possible. That they are not complied with is a well known fact, but this negligence means that after the first thunderclap thousands of people will storm dealers in radio equipment for protective devices and their meager supplies will be exhausted within a few hours.

One of the first questions that comes into the mind of the would be radio user concerns lightning. "Will my antenna attract lightning and cause my home to be struck?" he asks. To the general public wireless and lightning seem to be twin brothers—probably because the manifestations of both are uncanny and mysterious.

Hoisting a radio antenna over your property does not endanger your dwelling, your instruments or your family if a few simple precautions are observed. You have never felt apprehensive over the presence of the telephone wire running from the pole on the sidewalk to your house. You do not regard the bell wire circuit running from the front door to the kitchen as a lightning conductor, nor have you been nervous over the presence of a wire clothesline in your back yard, the tin roof over your head or the metal gutters and leader pipes.

All these common and familiar metal surfaces and conductors will convey electricity from point to point. The average radio antenna differs very little from these other conductors and objects, and in so far as lightning is concerned the radio antenna is much less likely to be struck during a heavy thunder storm.

Let us consider the electrical action that takes place in the antenna before and during a summer thunderstorm. There is always a certain amount of atmospheric electricity present in the air. In cold weather the amount is very slight and manifests itself in the radio set by what is familiarly known as static. When warm weather comes atmospheric electricity is generated in much larger quantities.

The intense heat of the summer sun evaporates the moisture on the surface of the earth and water from ponds and lakes very rapidly. This evaporated moisture or vapor, becoming heated, rises to the upper atmosphere and upon reaching the higher levels, where the temperature is lower, the water vapor condenses into minute drops of moisture and forms clouds. Each moisture particle becomes charged with a very small amount of electricity.

As the moisture particles in the upper air become more dense the particles crowd together and one particle combines with another. This combination increases the electrical charge on each particle until finally a thunder cloud is formed which is very highly charged with electricity.

It is a known fact that when thunderstorms are in formation electric discharges occur within the cloud. These discharges are popularly known as sheet lightning. Every time such a discharge takes place radio waves are emanated and these waves impinge upon your antenna, causing a sharp crash or crackle in the telephone receivers if you happen to be listening in.

A thunder cloud must be regarded as a huge bubble containing electricity. Discharges are constantly taking place within the bubble and increasing in size. When a certain critical point is reached the bubble bursts, the pent up electricity discharges in one swoop to the earth and we hear a mighty thunder-clap. If this lightning bolt strikes within one-half mile of your antenna, considerable current will be induced in your aerial system. This induced current will pass harmlessly to the ground and you will be unconscious of its presence if you have taken the proper precautions.

Let us consider the great bubble once more. If we prick tiny holes in this bubble while it is in process of formation, the pent up electricity will gradually discharge. If we prick enough holes in the bubble, the electric charge may leak away so fast that the quantity of electricity within may never reach the point where the bubble will burst. The function of the common lightning rod and the properly grounded or protected antenna is to prick holes in the great electric bubble in the sky and convey its charge silently to the ground. For this purpose the average radio antenna is exactly as effective as the lightning rod.

"What will happen if a lightning bolt actually strikes my antenna?" is a familiar question. Let us consider the nature of a lightning bolt. The heavy thunderclap which attends its appearance gives the impression of tremendous energy.

It is true that lightning is destructive, but as a matter of fact its bark deceives one of its might. The average lightning bolt contains about as much energy as represented in a pint of gasoline. The only difference is that the energy of lightning is exerted instantaneously.

Take, for instance, a cupful of gasoline and ignite it under a saucepan containing a tallow candle. The heat of the burning gasoline will melt the candle. The phenomenon is silent and harmless. Take another cupful of gasoline and dump it into the gas tank of the family flivver, crank up, and drive thirty miles an hour, head-on into a concrete wall. The effect is startling.

Even Henry Ford himself could not put together the remains and make them rattle once more. Yet the energy involved was no more than that necessary to melt the tallow candle.

A bolt of lightning represents an electrical collision. This accounts for its many strange antics, such as stripping the soles from shoes of persons struck, smashing crockery or ripping off wall paper.

Uses Electric Main to Pick Up Chicago

Few amateurs in this part of the country even with the best of aerials have been able to pick up KYW, the Westinghouse station at Chicago, not alone because of the air line distance of more than 700 miles, but also because of the interference of nearer stations on the same wave lengths. At least one radio listener in the city, however, who operates without any aerial on his roof, has caught the fleeting strains of the Illinois station.

Thomas C. Shotwell of 611 West 156th street, who has taken down his aerial and for more than a month has been getting all his concerts from an electric light socket, succeeded the other day in picking up KYW, but before long WJZ came crashing in from Newark and KYW ceased to sing. Other amateurs, following in Mr. Shotwell's footsteps by using an electric light socket, also have reported good results, but the system, as described by the Washington Heights experimenter, does not work in all sections of the city, and is not of value in the case of crystal detector sets.

Where the electric light mains are not grounded, attaching the antenna lead to only one of the two wires in the socket will not direct an electric current to the set, but where the mains are grounded there is danger that a current will shoot through the set, burning it out. Amateurs, therefore must proceed with the greatest care.

Mr. Shotwell suggested the possibility that the power house, in his case half a mile from his home, may act as a huge regenerative element picking up the messages and giving them radio amplification. In this case, he said, the electric light wire would simply conduct the waves, as in the case of Major-Gen. George O. Squier's wired wireless, to the receiving set. The electric light wires run underground and through the walls of the Shotwell apartment house, so that Mr. Shotwell cannot understand how it its that they act as a better aerial than the antenna he previously had on his roof.

Mr. Shotwell uses a Grebe CR6 set with radiotron detector and two stages of amplification.

A Wing that does the work of Two—

HERE'S a distinct advance in aircraft construction—the new Sperry Monoplane Wing.

If you are the owner of a Curtiss J-N, Canuck, or Standard J-1 this new wing will interest you. The product of the Lawrence Sperry Aircraft Co., it can be attached to your plane in place of the present wings in a few hours' time, and will nearly double the present carrying capacity of your machine.

In addition to its remarkable load-carrying ability and increased speed, this good looking Wing has the added advantages of unobstructed vision for pilot and passengers, and exceptional balance and strength. It is easy to assemble, and any seat in the plane can be reached by just stepping over either side.

Valspar furnishes the fine finish on the fabric of every Sperry Monoplane Wing. Valspar was chosen because it is waterproof and weatherproof, and because it combines remarkable elasticity with amazing durability under the severest conditions of air service.

Anything that's worth varnishing is worth Valsparring.

What Is Your Problem In Commercial Aviation?

GETTING STARTED?	All right, we have a stock of Airplanes and Motors ready to fly.
KEEPING GOING?	We can help you because we are the largest commercial aviation supply house in the country.
SERVICE?	Johnson Service means good service, including a modern equipped flying field and shop.
INFORMATION?	Our information department is at your service free of charge.
PRICES?	Lowest prices consistent with best material.
GUARANTEE?	Our customers must be satisfied always, or their money refunded.

Let us solve your problems in commercial aviation. Write us first and avoid costly delays. Our new catalog mailed on request.

A FEW SUGGESTIONS TO MAKE YOUR PLANE LOOK SNAPPY:

New Flottorp propeller, copper tipped......$30.00
New radiators, Curtiss or Standard 20.00
New upholstered wicker seats 3.00
New side cowl or cock-pit cowl Curtiss or Standard 15.00
New streamlined wheels, 26x4 .... 10.00
New Goodyear cord tires, 26x4 .... 10.00
New fuselage covers, ready to put on, Curtiss or Standard $15.00
New wind shields 2.50
New shock absorbers, per foot .... .05
New safety belts, American type 3.00
New center section with fittings, for Standard 10.00
New hose connections, all types .... .10
New hose clamps, all sizes ....$ .10
New Hartzell propeller, new design, brass tipped 60.00
New Warner tachometer with shaft 9.00
New thermometer, 15 ft. tube 7.50
New altimeters, 20,000 foot, luminous dial 10.00

2 SEATERS—JN'S $650.00 UP
Mercedes, Isotta or Hiso Standards $2500.00

NEW AVROS—$1250.00 to $1500.00
Single Seater—45 Anzani—80 Le Rhone
$450.00—$650.00

3 SEATER M.F. BOATS—HISPANO—$2000.

ALL PLANES EXCEPT SINGLE SEATER AND JNS NEW

What is a DH-6? It is an English training plane built for OX-5 motor. Span 36 ft., chord 6 ft., surface 418 sq. ft. Lands 30-35 m.p.h. and climbs 2000 ft. in 5½ minutes, loaded. We remodel them making two cockpits instead of one long one, install a new gas system and use forward stagger instead of back stagger, giving the ship a much better performance and appearance. It has about twice the factor of safety of a Canuck, lands 10 to 15 mi. slower than a JN, is more stable and easier to fly than a Standard Jl and will get in and out of even smaller places than an Avro. It has no equel for barnstorming, instruction or generel passenger work. Plenty of spares—cheap.
Our ships and prices must be right. 37 of 4 different makes sold since Jan. 1st., 1922.
DEALERS—Let's get together. We will work with you.

glass and automatically lighted in a certain order according to the direction of the wind. Such a system is possible, but very expensive.

The French organizations have tested another method for night landing. An oblong portion of the field is illuminated by a series of special searchlights in such a way that the major axis of the geometric figure formed by this illuminated portion lies in the direction of the wind. A red light placed beyond one end of this illuminated portion indicates the direction of landing, in order that all confusion may be avoided. The attached table gives the various signals employed on landing fields by day and by night.

3. *Signals for Foggy Weather.*—Since visual signals are useless in foggy weather, it is necessary to substitute sound or electro-magnetic signals. The use of the former is very limited, for the noise of the engines prevents their being heard on hoard. The latter are being investigated.

Conclusions

Regular and reliable aerial navigation is only rendered possible by the use of a suitable system of communications, signals and beacons along the air routes. These routes are nearly all international. The installation of their communications and beacons is therefore an international question and it is of the greatest importance for their development to have the various governments reach a complete agreement concerning the manner of establishing them. It is to be hoped that exchanges of views and discussions will increase between both private and public organizations for the development of aeronautics in the different countries. This can but help prepare the way for international agreements and hasten their realization.

Learn to Fly

Aviation is making such strides that it needs more men right now

You Can Learn To Fly

I can teach you how to become a successful pilot in a short time. My course is so arranged that you get only the things you need to make you a good aviator.

The Diggins Extension Course

is up-to-date, teaches you what you must know to become an expert flyer. This course is written by competent instructors right on my flying field. It is kept right up to the minute—all new developments in aviation are included. That is why it is recognized as the most complete and practical course offered today. My course saves you time and money because it prepares you at home so that you are ready to begin flying the day you arrive at the flying school.

Superior Points of the Diggins School

1. The Diggins school is the oldest, largest and most complete commercial aviation school in America.
2. The Diggins school is located in Chicago, the center of Aviation.
3. Living quarters and free employment service are maintained for students.
4. Diggins guarantees to make you a pilot.
5. Diggins' pilots get top notch salaries.
6. References, any aero club in America.

WRITE TODAY Write today for the new Diggins beautifully illustrated catalog.

The Ralph C. Diggins School of Aeronautics
Dept. 8 140 N. Dearborn St. Chicago, Ill.

Please send me the Diggins catalog and information about the Diggins flying course.

Evidence

THE fact that Aerial Age Weekly has by far the largest circulation of any aeronautic periodical in the United States is evidence of the fact that it carries the news while it is news and deals authoritatively with the many phases of world aeronautic progress.

It digests every aeronautic magazine in the world for the benefit of its American readers, and takes the story of American progress to the far corners of the globe.

Aeronautic events of great importance are pending and everyone who would be completely informed on the successive steps in the progress of these events should instruct us to place their names on our subscription list for the next year.

Simply sign the form below and we will do the rest.

AERIAL AGE WEEKLY,
5942 Grand Central Terminal, New York.

Please enter my name on your subscription list for one year and bill me four dollars (foreign six dollars) when service has been started.

Aeronautical Motor Forgings

(in various stages of completion)

For Sale by SEALED BID at Fairfield, Ohio, April 25th, 1922

Sealed proposals for the purchase of unfinished ferrous and non-ferrous Aeronautical motor forgings and castings and other scrap metals will be received at the Material Disposal & Salvage Section, Office, Chief of Air Service, Room 2626, Munitions Bldg., Washington, D. C., until 3.00 P. M. (E.T.) April 25th, 1922.

Description of Forgings

These forgings and castings are in various stages of completion, and appertain principally to Liberty 12 Motors. There are also a small number of Hall Scott and Curtiss Motor parts. Detailed list of the parts can be seen at Room 2626, Munitions Building, Washington.

The approximate metallic analysis of these forgings is:

Steel	545,643 lbs.
Aluminum	204,274 lbs.
Bronze	8,850 lbs.

This material is located at the Fairfield Air Intermediate Depot, Fairfield, Ohio. Inspection is invited.

Write also for detailed specifications of a large offering of lumber—white ash, white oak, hickory and elm, 700,000 bd. ft., for sale May 5, at Buffalo.

There will also be offered 7182 gallons of castor oil at Fairfield, Ohio, May 9.

Terms & Conditions of Sale

The material is offered for sale "as is, where is" on a gross too basis for the steel and a poond basis for the alominom and bronze. The minimum bidding onit to be coosidered will be for the eotire quaotity of the varous kinds of metal offered.

Cash or a certified check, payable to the Finance Officer, U. S. Army, represeoting ten per cent (10%) of the amount bid most accompany proposal. Material must be removed within 45 days from date of award.

For Proposal Blank and Full Information, write

Material Disposal & Salvage Section
Office, Chief of Air Service
Room, 2626 Munitions Bldg.
Washington, D. C.

Spring Flying Meet

A SPRING flying meeting held as a benefit for the Veterans' Mountain Camp attracted a crowd of more than 20,000 on April 30 to Curtiss Field, near Mineola, L. I. Foremost pilots in the country participated in events designed to demonstrate the fine points of the season's new models of aeroplanes. Twenty planes competed in the various races and tests. Between events pilots took spectators up for short "hops" around the field.

Otto H. Kahn, Assistant Postmaster General Paul Henderson, Major Gen. Mason H. Patrick, Chief of the United States Air Service, and Augustus Post, veteran balloonist, were among the spectators. The show was under the auspices of the Rotary Club of New York, assisted by the American Legion, the Aero Club of America, the Aeronautical Chamber of Commerce and the Curtiss Aeroplane and Motor Corporation, the last named, owners of the flying field.

Before the meet started Bert Acosta flew the Curtiss "Wildcat" at a speed of 208 miles an hour. The official world's speed record, established in France, is 203 miles an hour. As Acosta's feat was not officially recorded, it cannot be taken as a record.

There were ten contestants in an eight-mile flight over a triangular course. John Miller in a Curtiss Oriole won the first prize of $150, William Gillmore, second prize, $100, and A. Henrique, third, $50.

The spectators seemed to take the greatest interest in the performance of the Mummert, described as the smallest plane in the world. This plane has a wing spread of only eighteen feet and a length over all of twelve feet. Including the pilot, the total weight does not exceed 550 pounds, according to H. C. Mummert, the designer and builder. It was observed that only a short, thin pilot could sit in the tiny cockpit of the Mummert.

Contrasting with the Mummert was a huge Handley-Page twin-engined plane, seating twelve passengers in its enclosed fuselage. This plane, which was manoeuvred with seemingly remarkable ease, has a wing spread of ninety feet. During the afternoon the plane made several flights with invited guests as passengers.

One of the earlier Curtiss planes, which won the Gordon Bennett race in 1911, was flown at the meet and focussed attention on the strides that have been made in aeronautical development. The pilot, sitting on a bicycle-like seat, seemed suspended in the air. The manoeuvreability of this machine won the admiration of pilots about the field.

The postal air mail had six planes at the field for the inspection of the public. Assistant Postmaster Henderson, who is in charge of the air mail, announced that probably during this Summer aerial night flying mail service between New York and San Francisco would be established.

"The Air Mail Service cannot be improved without night flying," he said. "I am at present at work planning emergency landing fields across the continent at thirty-mile intervals. These fields will be lighted with beacons and flares, the latter turned on when a plane desires to land. The air mail planes will be equipped with radio directional finders and radio telephone."

Major Gen. Patrick, while watching the flying, called attention to the advance of the Orient in demonstrating the utility of the aeroplane in attack. He said what the Chinese had accomplished the latter part of the week was significant and prophetic of what would happen in wars of the future.

Rates in France to be Cut for Tourists

WITH the assurance that at least 300,000 Americans will cross Europe this season, most of whom will want to have as much time as possible in traveling across France, Belgium and Germany, aeroplane companies here are preparing to slash prices in an unprecedented battle for clients.

Already the companies crossing the Channel have lopped off 50 francs and are considering another decrease early next month which will bring the cost to the level of that of first class railway and steamship accommodations, with a saving of at least five hours between London and Paris.

Not only is this arrangement to apply to the regular schedules but the air station at Le Bourget is being equipped to accommodate at least 200 planes, which will be ready to leave in any direction at any hour, with pilots certified by the French Government.

The machines will be big enough to take ten passengers each in the great rush which is expected late in the summer, when trains are overcrowded and there are the alternatives of standing up all night or altering plans to visit the most cherished scenes.

Travelers generally, however, will find the railways anxious to give better service than last year. Although the rail tariff has not yet decreased, officials declare they are preparing for tourist traffic on a greater scale than ever before.

THE NEWS OF THE WEEK

Captain of R-38 on Visit Here

Capt. Archibald H. Wann, who was in command of the giant British dirigible R-38, which was to have been known as the American ZR-2, when she fell into the Humber River at Hull, England, last August, carrying sixteen Americans to death, arrived recently on the Celtic.

Capt. Wann was accompanied by his brother, Major James Wann, also of the British Air Service. He was extremely reluctant to talk about the accident to the R-38, but admitted he had confidence in such dirigibles and looked forward to the day when they would be safe for travel.

"England hasn't given up building dirigibles," said Capt. Wann. "Her failure to build them now is due to lack of money and not lack of confidence. There must be accidents when experimenting."

He pointed out that Germany had fourteen very serious accidents before she successfully used the Zeppelin in the World War. Capt. Wann is here in an unofficial capacity. He and his brother came to this country to visit another member of his family, who is in business in this city.

Aviators' Ball in Airdrome Setting

The fourth Aviators' Ball was held at the Astor, New York City, April 24, and was largely attended, with a brilliant representation of society and officialdom from the State and New York National Guard. The ball was opened with military ceremonies, Mme. Eleanora de Cisneros singing the national anthem. Many high ranking army and navy officers and the presence of most of the allied aviators in uniform, with their decorations, marked the military and patriotic of the ball.

The ballroom of the Astor was transformed into an airdrome, somewhere in France, for the ball, and represented the landing field, with the national colors at one end and the air direction sleeve, a part of every airdrome's equipment, at the other. An electrical cloud effect and numerous miniature aeroplanes added to the realism of the background.

Many dinners preceded the function, among the dinner hostesses being Mrs. T. J. Oakley Rhinelander, Mrs. E. N. Breitung, Mrs. George D. Yeomans, Mrs. Malcomn Sloane, Mrs. Edwin Shattuck, Mrs. Harry Harkness Flagler, the Misses Barbara Brokaw and Dorothy Collins. Colonel Laurence L. Driggs, general Chairman of the ball, also entertained at dinner.

A feature of the evening was a pageant of the air presented under the direction of Francis Markoe, assisted by the Misses Dorothy Collins, Barbara Brokaw and Marjorie Cleveland. Those who took part in the pageant were the Misses Constance Banks, Elizabeth Andrade, Beatrice Batterman, Phyllis Batchellor, Alice Beadleston, Harriet Camac, Dolores Carillo, Nina Chatillon, Elizabeth Clarke, Florence Clendenin, Margaret Davison, Emily Dodge, Mrs. Henry Rogers Benjamin, Mrs. Howard Burdick and Mrs. Fal de Saint Phalle.

Incidentally professional dancers from current theatrical attractions appeared. Mlle. Stasia Ledowa, premiere danseuse of the Chicago Opera Company, danced "The Day of a Butterfly."

Mrs. Charles Dana Gibson was Chairman of the Patroness Committee. Among the patronesses were Mrs. Henry M. Alexander, Mrs. Cortlandt Field Bishop, Mrs. Robert Bacon, Mrs. John Barber, Mrs. Charles de Rham, Jr., Mrs. Newbold LeRoy Edgar, Mrs. Marshall Field, Mrs. Henry H. Flagler, Mrs. R. Horace Gallatin, Mrs. Jay Gould, Mrs. E. H. Harriman, Mrs. F. Burrall Hoffman, Mrs. Goodhue Livingston, Jr., Mrs. John Purroy Mitchel, Mrs. Theodore Roosevelt, Jr., Mrs. H. Rivington Pyne, Mrs. Herbert Shipman, Mrs. Henry Rogers Winthrop and Mrs. Charles C. Rumsey.

Monmouth Flying Meet

A flying meet will be held at Monmouth, Illinois, June 15 to 17th by the Monmouth Aero Club assisted by The Curtiss Iowa Air Craft Corporation of Fort Dodge, Iowa, owners and operators of the flying field at Monmouth. Major R. W. Schroeder will act as judge of the meet and will fly to Monmouth from Chicago with Mrs. Schroeder.

Many prominent fliers and manufacturers have accepted invitations to attend this meet and there is every assurance that it will be the biggest event of its kind ever held in Illinois outside of Chicago.

Major F. H. LaGuardia Addresses Aeronautical Executives

On Friday, April 21st, the Executives of the Aeronautical Companies in the vicinity of New York attended their seventh semi-monthly luncheon at the Café Boulevard.

Major LaGuardia was introduced to those present by the Chairman, Mr. R. R. Blythe who stated in his introduction that as the Major has been for years in political prominence and recently Colonel of the New York Aerial Policy, that his brilliant career was known to all.

"The future of Commercial Aviation is merely a question of time," pointed out Major LaGuardia. "There is no doubt in my mind but that we are on the verge of a very great development in Aeronautics; this, nevertheless, must come from within the industry itself. We cannot expect future large appropriations from the Government to sustain orders for planes and motors and thereby tide the industry over to better times. As times goes on the Government orders will be decreased, the aircraft budget will be cut to a minimum.

During the War when the Government took over the railroads there was a great deal of criticism for the Administration, but few people realized that the Government agreed to pay five per cent. interest on all the railroads' funded debt. In this, to a great extent, was the Government Railroad deficit increased. Now, just as the railroads were taken over in the past so will they be again in the future owing to the fact that slowly the interest on the railroad debt is mounting up and it is becoming increasingly harder to operate at a reasonable cost. When freights become excessive the Government will have to take a hand; the waterways of the United States will be utilized for slow freight, trains for regular freight and aircraft for express.

"Passenger carrying," said Major LaGuardia, "is the least remunerative of any form of transportation, it incurs greater expense, improved facilities, and more space than express or freight.

"It therefore, remains that those executives in the industry who are desirous of more rapid development to secure Government Mail Contracts and cater to fast express. Time and confidence will bring the passengers to our Central Air Depots."

The Portugal-Brazil Flight

Rio de Janeiro—The Portuguese aviators who were attempting a flight from Portugal to Brazil, will be unable to proceed in their hydro-aeroplane from St. Paul Rocks, a few hundred miles short of their goal on the American Continent, where they landed April 18 because of damage to their machine, according to a Havas dispatch from Pernambuco.

The message says their hydro-aeroplane was so badly damaged in effecting the landing that it is no longer usable. The aviators, however, expect to save the motor.

Another agency dispatch from the island of Fernando de Noronha, confirming the loss of the hydro-aeroplane, says the aviators are ready to resume their voyage and are confident of successfully completing it if the Government will furnish them with another machine.

Captains Coutinho and Sacadura started from Lisbon March 30 on their attempted flight to Brazil. Their first jump was to Las Palmas, in the Canary Islands, 710 miles, which they covered in seven and one-half hours. Delayed several days by bad weather, they finally hopped off from Gando Bay, in the Canaries, on the morning of April 5, for the Cape Verde Islands, some 800 miles distant, and reached St. Vincent, in the Cape Verdes, that afternoon.

There was further delay at these islands while favorable weather conditions were being awaited, but at 5:50 o'clock Tuesday morning, April 18, the airmen set off from Porto Praya, in the Cape Verdes, for St. Paul Rocks, about 900 miles distant, in mid-Atlantic. They reached their destination at the rocks at 8 o'clock Tuesday evening, but had a misadventure on landing. The dispatches Tuesday night, however, reported their machine was only slightly damaged.

From St. Paul Rocks the aviators intended flying to the islands of Fernando de Noronha, off the Brazilian coast, after replenishing their gas supply. The next leg of their flight would have brought them at Fernando de Noronha, within about 275 miles of Pernambuco, their intended destination.

The Aeroplane as a Time Saver in Business

One of San Francisco's most successful business merchants, Mr. James Otis, to whom time, in a very literal sense, means money, realizing the value of the aeroplane as a successful saver of silver seconds, substitutes for a high-powered roadster in which to travel from place to place on important business missions, his 2-passenger Ansaldo "Airster." Through the courtesy of Mr. Otis, several ladies of Crissy Field were treated to a "hop" in the Ansaldo recently. One or two of the intrepid aviatrices were seasoned aerial navigators—they had been up at least once or twice before! The Ansaldo "hop," however, provided the others with their initial aeroplane "thrill."

The AIRCRAFT TRADE REVIEW

American Air Service Company Plans

Major Charles J. Glidden, President of the World's Boards of Aeronautical Commissioners, Inc., at the banquet of the Publicity Club at Springfield, Mass., said:

"After inspecting the landing fields—and possibilities of Springfield, that on account of its geographical position Springfield is bound to be a distributing point for Air Mail Merchandise and passengers to all parts of New England States to points in Vermont, New Hampshire, Eastern, Central and Northwestern Massachusetts points; also Maine and the North Eastern Provinces as far as New Brunswick and Newfoundland, and Canada from Montreal to Three Rivers and Quebec.

"The aeroplanes from New York will fly express to Springfield, where the merchandise will be transferred in hampers and the mail in sacks to planes covering the area above mentioned. Therefore it is very important that Springfield should keep close in touch with the aeronautical movement.

"The Committee on Investigation and Organization of the American Air Service Company to be incorporated to operate a line from New York to Chicago and the Pacific Coast are making splendid progress. This committee of which I have the honor to be Chairman was appointed at the Biltmore Hotel meeting February 11th. The meeting was addressed by Mr. Milton A. Stone of your City and Chairman of the World's Board of Aeronautical Commissioners, Inc., for Massachusetts, Congressman Steenerson, Chairman Committee on Post Offices and Post Roads, special representatives sent to the meeting by the Postmaster General, Secretary of the Navy, and others.

"This line will be extended to Springfield, Boston and the Provinces, and we hope to start a daily test service within the next sixty days each way between New York and Chicago, carrying first, mail and merchandise, later passengers.

"The ships will fly at night, leaving Chicago and New York about midnight, arriving in the early morning. Bankers say this will save $100,000 daily in interest charges on bank clearings.

"Following the test flights, permanent service will be established between New York and Chicago. The test flights will then be put into operation between Chicago, San Francisco, Los Angeles, Seattle, New Orleans and other points."

General Theory of Thin Wing Sections

This report (No. 142) of the National Advisory Committee for Aeronautics by Max M. Munk deals with a new, simple method of calculating the air forces to which thin wings are subjected at small angles of attack, if their curvature is not too great. Two simple integrals are the result. They contain only the coordinates of the wing section. The first integral gives the angle of attack at which the lift of the wing is zero, the second integral gives the moment experienced by the wing when its angle is zero. The two constants thus obtained are sufficient to determine the lift and moment for any other angle of attack. This refers primarily to a two-dimensional flow in a non-viscous fluid. However, in combination with the theory of the aerodynamical induction, and with our empirical knowledge of the drag due to friction, the results are valuable for actual wings also. A particular result obtained is the calculation of the elevator effect. The following is an outline of the subject as treated in this report:

I. Introduction.
II. Calculation of the elevator effect.
III. General formula for any section.
IV. Examples of the zero angle.
V. Thin sections with upper and lower boundaries.
VI. The moment coefficient.
VII. Examples of the moment coefficient.
VIII. Table of the sections investigated.

A copy of Report No. 142 may be obtained upon request from the National Advisory Committee for Aeronautics.

Progress of Aeronautics in Congress

The Aeronautical Chamber of Commerce has prepared the following memorandum concerning the progress of aeronautic matters in Congress.

March 13, *Senate.*

Mr. McKellar introduces S. J. Res. 175 relative to the purchase of aircraft from any foreign nation, citizen, or corporation.

March 21, *House.*

Executive document 572, transmitting supplemental estimate of appropriation for the Navy department for the fiscal year ending June 30, 1923, for salaries: "Bureau of aeronautics" 56,010, as a substitute for the estimate contained in the Budget of $43,310, and for "care, custdoy, and operation of the naval petroleum reserves," $100,000 (H. Doc. No. 218); to the Comm. on appropriations.

March 22, *House.*

Mr. Larsen introduces into the record a letter from an attorney (H. W. Driscoll) to an aviator suggesting that he appoint him attorney to collect back pay made possible by a recent decision of the Court of Claims. The fee was to be one-third of the amount collected. For all the cases involved as a result of this decision, the lawyer would receive about $1,000,000 for his services on the basis of one-third of the amount collected.

March 24, *House.*

Army appropriation bill debated. The need of helium investigated and more extensive experimental work at McCook Field debated.

March 29, *Senate.*

Mr. Hurd in discussing the Naval Disarmament Treaty emphasizes that the day of the battleship is over and that the aeroplane is one of the new weapons of warfare.

April 3, *Senate.*

Mr. Walsh of Massachusetts introduces a Resolution (266) proposing the establishment of a school of aeronautics.

April 5, *Senate.*

Mr. Walsh's resolution (see above) read again and laid aside for more complete data.

April 6, *House.*

Mr. Steenerson (H. R. 11193) to encourage commercial aviation and authorizing the Postmaster-General to contract for air mail service and prescribing rates of transportation and postage thereon; to the Committee on the Post Office and Post Roads.

April 11, *House.*

Mr. Woodruff introduces a resolution authorizing a Committee to investigate war contracts and expenditures. Brings into the discussion the subject of aircraft contracts.

April 12, *House.*

In discussing the the navy bill (H. R. 11228) the question of the no. of personnel in the navy service was brought up. Mr. French believed there was no basis of comparison between the British air force and the American as the British was an offensive force and ours is a defensive force.

April 18, *House.*

In discussing the Navy appropriation bill (H. R. 11228) the aviation appropriations were discussed. The bill calls for a total of $7,866,950. Mr. Hicks offered an amendment increasing the sum provided for overhauling planes from $5,475,000 to $7,093,000.

April 19, *House.*

Amendment of Mr. Hicks rejected (See above).

COMING AERONAUTICAL EVENTS

AMERICAN

May	—National Balloon Race.
Sept. 4 (*about*)	—Detroit Aerial Water Derby, Detroit. (Curtiss Marine Flying Trophy Competition.)
Sept. 15 (*about*)	—Detroit Aerial Derby, Detroit. (Pulitzer Trophy Race.)
Sept. 30	—First Annual Interservice Championship Meet. (In preparation.)

FOREIGN

Aug. 1 (*about*)	—Coupe Jacques Schneider. (Seaplane speed race.) Italy, probably Venice.
Aug. 6	—Gordon Bennett Balloon Race, Geneva, Switzerland.
Oct. 1	—Coupe Henri Deutsch de la Meurthe. (Aeroplane speed race.) France. American elimination trials, if required, to be held about Aug. 15, at Mitchel Field, L. I.

Digitized by Google

MAPS AND NAVIGATION METHODS

By A. DUVAL*

BEFORE undertaking any voyage, however short, the aerial navigator provides himself with the necessary maps. This is an easy matter in our country, where there is a wide choice among the various maps published by the Geographic Section of the Army, the Department of the Interior and the Aero Club.

When it is a question of a trip into a foreign country, the case is no longer the same. In some countries the only existing maps are incorrect or poorly edited, while in others they are comparable with ours, but French navigators, not being accustomed to their scales, nor to their colors, nor to their special manner of presentation, do not find them convenient. Reciprocally, foreigners experience the same inconvenience in using our maps. The most commonly used map is drawn on the scale of 1 : 200,000. This gives the most details of interest to the aviator, without taking too much paper. The 1 : 1,000,000 scale is useful for long voyages. It is always best to carry the corresponding maps on the 1 : 200,000 scale, for the aerial navigator sometimes has occasion to identify details not shown on the 1 : 1,000,000 map.

These two maps are not specially made for aviators. It seems therefore that the solution of the problem has progressed hardly any since Mr. Lallemand, member of the Institute, asked for the creation of aviation maps. This delay is explained by the fact that during the war the existing maps (1 : 200,000 of the Geographic Section of the Army, and 1 : 126,720 of the Ordnance Survey") were satisfactory to the aviators of the allies, who flew in restricted sectors and seldom made long voyages.

Now the requirements of civil aeronautics, the chief object of which is to make voyages are different and depend on aviation maps. This fact did not escape the attention of the experts who drew up the international agreement of October 13, 1919, containing regulations for aerial navigation. Annex F, of this agreement or convention, made provision for various international aviation maps, which the contracting countries will publish within a few years. Already three of the most enterprising nations have agreed on the details of execution, as we shall see further along.

Anyway, it is not out of place to call attention to the scope of the task undertaken, as well as to the value of the preliminary work accomplished since 1919. If the aviators, who are wanting aviation maps worthy of the name, had any idea of the work accomplished, their very natural impatience would be less prompt to manifest itself.

Under the respective designations of normal maps and general maps, the convention established two types of international aviation maps. In principle, they must be made according to the rules adopted for the 1: 1,000,000 map of the world, with the metric system of measurements. Each country, however, has the privilege to *add* its own units of measurement to the maps it publishes.

After discussion during the English-French-Belgian conferences of 1920 and 1921, the details of the conventional symbols were fixed. Since their exposition lies outside the scope of this article, we will confine ourselves to a general description of the two kinds of maps provided for.

General maps.—The general map is made according to Mercator's projection, one degree of longitude being represented by a length of three centimeters, which gives, in our latitude, an average scale of about 1 : 2,000,000. Each folio contains a complete number of sections of the map of the world on the 1 : 1,000,000 scale, which is generally nine for latitudes below 60°, six and even three for higher latitudes. Each side of each sheet covers 1° in latitude by 2° in longitude. There is a common portion on adjacent sheets, which facilitates the passage from one sheet to the next.

The relief is indicated by hypsometric tints supplemented by altimetric figures and, where there is occasion for it, by a slight shading. This method of representing the relief is in conformity with the 1 : 1,000,000 map of the world. It enables the aviator to choose instantly, without risk, the altitude of safety, in case of poor visibility. Any representation of relief, accomplished simply by means of shading and altitude figures, does not offer this advantage, since the navigator must read all the altitudes of a region in order to determine the altitude of safety. He runs the risk of overlooking that of the summit, against which he is in danger of crashing. The necessity of judging the altitude of the whole region led to the use of hypsometric colors for the general map. It is omitted on the normal maps, where each section bears on its margin the altitude of the highest point and of the lowest point in the region represented. The relief of the normal map is also shown by shading

Lastly, general maps are only provided for continents. Aviation maps are not necessary, in fact, for the oceans, for which the aeronaut will use marine maps based on Mercator's projection.

Normal maps.—These are published on the scale of 1 : 200,000. The kind of projection is not stipulated. This is because, on the one hand, the various projections differ but little on this scale and because, on the other hand, of the great advantage of being able to make use of much existing cartographic material.

Each section of the normal map embraces 1° in longitude and 1° in latitude. They will doubtless overlap one another by several kilometers. The relief is indicated by shading, supplemented by altimetric figures.

Miscellaneous maps.—The object of the convention was to create a set of identical aeronautic maps for the whole globe. Aside from these standard maps, the aerial navigator may use any others. Let us note, in passing, the 1 : 200,000 map of Capt. Hebrard and Lieut. Robbe, on which the roads stand out light against a dark background. The advantages of this method will be manifest, when night flights become common.

Maps are indispensable for the aviator. Their conception, however, depends on the methods employed in aerial navigation, which we will now endeavor to set forth.

"To navigate is to go from one point to another by the shortest and easiest route." This applies to both water and aircraft.

Aerial navigation, although freely accomplished in three dimensions (with certain restrictions in the vertical direction) is in all points comparable with maritime navigation. On the contrary, it is not comparable with the means of land transportation.

In fact; there are two methods of navigating an aircraft:

1. To fly with continuous reference to landmarks;*
2. To take a direct route by the compass, with only occasional reference to the ground for determining the position of the aircraft.

The former method, which is chronologically older, is still commonly employed. Although comprehensible in the beginnings of aviation, when only the pilot was on board and the voyages were of short duration, it is now an anachronism. To be compelled to follow a railway or a river is a loss of time. This method is, moreover, not very safe, for as soon as the pilot loses this "thread of Ariadne," he is lost. Errors have been frequent at cross-roads and junctions. Lastly, it is well to note the danger resulting from this practice. On a given aerial route, all the pilots would follow, in cloudy weather, exactly the same landmarks, thus creating great risk of collisions.

The second method, successfully employed on aeroplanes and airships by several crews, has stood the test for centuries in all navies. It is therefore no novelty, but merely an adaptation. By means of the compass, the pilot steers the aircraft in a constant direction with reference to the meridian. The path thus described is a loxodromic or rhumb line.

Hence, to steer by the compass is to describe a loxodromic curve. The pilot only needs to choose the one which connects his starting point with his destination, and then to make sure from time to time that he has not departed from it and, lastly, to verify his speed.

The use of the compass renders it possible to follow the most direct route between two points and especially to lose sight of land without inconvenience, for a certain length of time. At any instant, the navigator can determine his position by "dead reckoning," with the aid of his absolute speed and the time elapsed.

The accuracy of this method depends on the pilot's skill in using his compass and on the exactness of his knowledge of

*From "Premier Congrès International de la Navigation Aérienne," pp. 150-155, Paris, November, 1921.

*Some authors make a distinction between following a continuous reference line (highway or railroad) and flying from one reference point to another by comparing the ground and the map. This is a distinction without a difference, since in cloudy weather they lead to the same result, flight near the ground.

*Some authors make a distinction between following a continuous reference line (highway or railroad) and flying from one referenee point to another by comparing the ground and the map. This is a distinction without a difference, since in cloudy weather they lead to the same result, flight near the ground.

Digitized by Google

the data employed, namely, the angle of the route followed and the absolute speed. The route angle is the angle formed with the meridian by the loxodromic trajectory described on the earth by the aircraft which is steered with the aid of the compass.

As often as possible, this dead reckoning will be verified by observations of terrestrial or celestial reference points, or other method (radiogoniometry, etc.).

Usually the wind causes the aeroplane to drift (uniformly, if the wind is regular). The angle between the axis of the aircraft called the course, and the route actually followed is the angle of drift. The pilot must therefore endeavor to determine the course to be adopted so that the drift will cause him to follow the loxodromic line traced on the map. Practically, for holding the aircraft on this course, the pilot must determine opposite what graduation of the compass rose he must hold the reference mark which indicates the position of the axis of the aeroplane. The compass course is obtained by correcting the given course by the angle of "variation." This variation is the algebraic sum of the magnetic declination (angle formed, at any given place, between the geographic and magnetic meridians) and the deflection caused by the iron of the aircraft, which affects the magnetized compass needle. The declination is always exactly known. As to the deflection, an endeavor should be made to eliminate this once for all by "compensation," the explanation of which lies outside the scope of the present article. It is a very simple and practical operation. When properly executed, the residual deflection is very small (1° to 2°) and the directive force of the compass remains constant for different courses.

The only difficulty encountered in following a loxodromic or rhumb line is therefore the determination of the angle of drift. By means of aerological soundings, this is easily determined before starting. The data for calculating the course then remain exact so long as the wind does not vary. If the wind is found to change, it becomes necessary to change the course steered or be driven off the true route. During the voyage, the navigator must employ one of the two following methods for determining the drift.

1. Determination, on the map, of two successive positions of the aircraft and of the exact route followed between these positions.

2. Instantaneous measurement of the drift by the observation of some point on the earth.

The first method utilizes what some call "navigation by observation," in which the navigator steers by calculation, which he rectifies by every observation made. He thus describes a series of loxodromic lines each one starting from the last point observed.

The second method of measuring the drift necessitates a brief view of the earth, without its being necessary, however, to identify any given reference point. It consists in measuring the angle formed by the apparent motion of the reference point and the course of the aircraft. This measurement can be made, even when the reference point does not pass directly under the aircraft. The S.T.Ae. (Technical Section of Aeronautics) drift-meter and the Le Prieur "navigraph" are based on this principle. Moreover, the results are faithfully preserved, which constitutes a great advantage, since two successive drift measurements with different courses give the magnitude and direction of the wind.

The absolute speed is measured: either by noting the time taken to traverse the distance between two observed points, which are shown on the map; or instantaneously by making measurements with reference to a single point, which does not need to be identified.

For utilizing the latter method, we may employ the navigraph, the S.T.Ae. drift-meter, or the Le Prieur "cinemograph."

In the S.T.Ae. drift-meter, there are two sighting wires, adjustable in altitude, which intercept a base of 500 km. on the ground. The navigator sights a reference point and measures with a chronograph the time of passage from one wire to the other. An abacus gives the absolute speed in km/hr.

In the Le Prieur cinemograph, the sighting is done with the aid of a slide carrying a stylus which traces a line on a paper moving vertically with a uniform speed. These combined uniform motions give a straight line, the inclination of which is a function of the altitude and of the speed. The errors due to changes in the trim of the aircraft are elminated by the fact of the graphic inscription.

In the navigraph, the absolute speed is obtained by the automatic production of the triangle of velocities, of which the sides "air speed" and "wind" are known, as also the angle of drift.

Observation point.—This can be obtained by watching the ground. The navigator either identifies some reference point under him or determines his position with the aid of distant reference points.

When the ground is not visible, the observation point is found by observing the stars, according to methods similar to those employed at sea. Unfortunately, the mariner's sextant is not utilizable on aircraft and no other instrument has thus far afforded any practical solution of the problem. For want of an astronomical point, the aerial navigator can utilize radiogoniometry.

The preceding exposition shows that loxodromy is the basis of aerial navigation. The ideal map for aerial navigation is therefore the one on which all the loxodromes are represented by straight lines and their angles with the meridians. Only Mercator's projection will answer these requirements. Its use for general aeronautic maps is therefore fully justified.

As regards utilizable routes in aerial navigation, we have purposely omitted orthodromy (sailing on the arc of a great circle). The arc of a great circle is in fact the shortest way between any two points on the earth's surface and would therefore seem preferable to loxodromy. This advantage is, however, only theoretical, since for all points less than 1,000 km. (622 miles) the difference between the orthodrome and loxodrome is negligible (about 1/300). Now, the stops, the obligatory points for crossing frontiers, and natural obstacles impose an itinerary, whose sections rarely attain 1,000 km. These sections are therefore loxodromcs.

There remains the employment of orthodromy on very long trips. Here again flight on the arc of a great circle does not make good its promises. If the points of departure and arrival are on the same parallel of latitude, the vertex or culminating point of the curve is near the pole and hence climatic considerations prevent the utilization of the most important part of the ideal curve. If the points of departure and arrival are almost on the same meridian or near the equator, the orthodrome and loxodrome differ but little. It should be noted, moreover, that the only method for describing a great circle consists in resolving it into a series of successive loxodromes of about 1,000 km. which are followed by means of a compass.

The arc of a great circle therefore serves to determine an itinerary. There is no need of special maps for this purpose, since Mr. Favé, a member of the Institute, has invented a rapid and simple method of tracing the arc of a great circle on a Mercator map. The employment of the Favé abacus enables the aerial navigator to determine instantly and accurately the points through which an arc of a great circle passes by simply moving over the map a transparent sheet on which is traced a whole series of curves representing the projection of various great circles whose vertices are on any given meridian.

In conclusion, we may say that, on the one hand, the question of aeronautic maps is progressive and is following its normal course; while, on the other hand, the empirical methods of aerial navigation thus far employed are retrogressive, slow and dangerous and should be replaced by scientific methods of navigation, based on loxodromy and the use of the compass.

(Translated by the National Advisory Committee for Aeronautics.)

STANDARDIZATION AND AERODYNAMICS

By DR. TRIZ. RICHARD KATZMAYR

Aerodynamical Laboratory of the Technischen Hochschule of Wien, Austria

WITH reference to the suggestion made by W. Knight in the AERIAL AGE, of June 20, 1921, for calling a congress of representatives of aeronautical laboratories in Europe and in the United States in order to arrive at an international agreement on the subject of wind-tunnel experimental work and standardization of aerodynamical terms and symbols used in aeronautical technical works, I wish to express the point of view of both Prof. Triz. Richard Knoller and myself on this subject.

After the very interesting discussion in the AERIAL AGE, by Prof. Prandtl (Oct. 3, 1921), by Prof. Karman (Jan. 2d, 1922), by Col. Costanz, (Feb. 20th, 1922), by Mr. Margoulis (March 6th, 1922), and by Col. Verdugio (April 3d, 1922) of Mr. Knight's article on "Standardization and Aerodynamics", I think it is well to state the stand taken on this matter by our laboratory.

In the issue of AERIAL AGE, which appeared on October 3d, 1921, Prof. L. Prandtl insisted on the absolute necessity of

Digitized by Google

having an airstream of great constancy and freedom from eddies if wind-tunnel experiments are to have any practical value, and showed how such an ideal airstream can be obtained in practice. As a matter of fact the wind-tunnel of the Aerodynamic Institute, at Göttingen happens to be one of the few that permit such excellent conditions, and it should not be difficult to build all future wind-tunnel installations to give equally good results, if Prof. Prandtl's carefully-prepared specifications be closely adhered to. In the great majority of existing laboratories the airstreams that can be obtained with present apparatus are all but even, yet it would be uneconomical and too radical to consign them to the scrap-heap forthwith for that reason.

It would be of great value, however, if it were possible to compare without further question results obtained upon similar models in different laboratories, and this is quite within present possibilities. It would only require the testing of a number of standard bodies (such as spheres, fusiforms and one or two aerofoils), for their aerodynamic characteristics in all the leading laboratories and to compare results. To insure accuracy and to prevent slight differences in the models that might affect their behavior under test, the same set of models should be used in each experiment, no matter where performed. The several results thus obtained could then be used to establish what we might call a "laboratory factor" or a constant which would express all those elements which are peculiar to the laboratory in question and which cannot be deduced mathematically, as turbulence, proportion of model to area of airstream and especially the influence of the means for fastening the model to the balance. It is not sufficient to test merely a sphere, as was suggested, as such investigations as have been made with wing models have given different results. At the present time a series of comparative tests is being made between the laboratories in Vienna and Göttingen and it is intended to send the models to all the other wind-tunnels in Germany to obtain a better basis for comparison. It would be advisable to have this matter taken up by an international committee so as to include all the leading European and American institutions.

Attention should be called to the fact that for practical purposes it is not always advisable to employ a current that is totally free from eddies, such a condition is never prevailing in free flight. The degree of turbulence in the Vienna wind-tunnel *happens* to be such that the results therein obtained can be adopted without further correction, and several comparisons of full-sized machines with their models (usually in 1:15 ratio) have shown a remarkable correlation of the actual flight performance with the results calculated from wind-tunnel tests. It was noticed that an increase in turbulence has the same effect as the increasing of $\frac{vi}{v}$, which fact is of importance to laboratories of small dimensions and comparatively slow air-speeds, which are thus enabled to give satisfactory results with lower cost of construction and maintenance. For purely *theoretical* measurements, however, an airstream without turbulence is essential.

Regarding the size of the models and the best airspeed to be used, it may be observed that the results obtained during the past 10 years in the Vienna laboratory with a standard aerofoil of 900 x 150 mm. and in an airstream of 18 meters per sec. have proven very satisfactory.

Of great importance is the correct fastening of the models in the airstream. They should be so secured that the flow around the model is not disturbed, and yet a very stiff and inflexible mounting is essential. At Vienna this is obtained by means of four wires and a stream-lined supporting rod 2.5 millimeters thick.

In AERIAL AGE, of October 3d, Prof. Prandtl commented upon the advantages of reducing the airspeed to the equivalent expression for height ($\frac{V^2 g}{2}$) as first proposed in 1914 by Prof. Knoller and adopted by all German laboratories since 1917. He also advocated the general introduction of absolute coefficients.

One of the most necessary tasks of such an international committee is the standardization of aerodynamic definitions and units. Without prejudice toward the labor of the future committee the most widely used expressions and their generally accepted meaning may be summarized here.

In Austria the following symbols hav been decided upon:

$p = \frac{V^2}{2} g$ = Velocity pressure, dynamic air pressure, head.

v = resultant velocity, flight speed in meters per second or feet per second.

V = the same in KM per hour or M. per hour.

F = Wing surface or wing area.

R = Resistance.

A = Lift.

W = Drift.

N = Normal force.

T = Tangent force.

${}^cR$, ${}^cA$, ${}^cW$ = Unit air resistance, unit lift, unit drift, or absolute coefficient of res., lift or drift.

e = Center of pressure.

M = Ne = Torque.

E = Ratio $\frac{W}{A}$

X = Angle of incidence.

The following is an exposition of the choice of the above symbols:

p stands for "velocity pressure", and is well nigh international (*p*ressure in English, *p*ression in French, *p*ressing in German) being derived from the common Latin root *p*remo (to push).

v and V for "velocity," derived from the Latin "velocitas."

F for surface, with reference to the English and French (sur)*f*ace and the German *f*läche, all of which are derived from "*f*acies".

R was chosen for "*r*esistance", a word identical in most languages; also stands for the German "*r*esultierende" (resultant).

Hitherto R was resolved into its components L (lift) and D (drift), corresponding to the French R_y and R_x and the German A and W, the assumption being that L is perpendicular and D parallel to the line of flight. To speak about "lift" in this sense, however, is not strictly correct, inasmuch as a strict interpretation of that word assumes a force that is vertical with respect to the horizon and is equal and opposite to gravity, which condition in actual flight is but seldom true. It would therefore be advisable to use another symbol in every language. Prof. Knoller proposes to replace "lift" by "shear"—as expressing more correctly the action of a force which is perpendicular to another force independently of the latter's direction in space. The word "shear" being an engineering term meaning a force acting perpendicularly to the grain of a given material (German for shear = "*s*chubkraft"). S would be a better symbol in spite of the fact that the corresponding French word is "cisaillement."

The present symbol for *d*rift or *d*rag could be retained, and the present German expression (rücktrieb) could be replaced by "*d*ruck", meaning to pull or pressure, and a mathematically more correct expression. D therefore fits all languages and should be retained. Another proposal made by the present writer would substitute Z and X for L and D. The advantage thereof lies in the internationally understood application and the fact that the resistance R is actually resolved into two components which are vertical only to each other and belong to a system of coördinates of which the X axis is parallel to the line of flight. The aerodynamic expert is already familiar with the practice of referring moments of stability to this system, the axes being assumed to be identical with the theoretical axes of the machine itself.

The symbols N for *n*ormal force and T for *t*angent force are internationally self evident and require no explanation.

As Mr. Knight has observed, the greatest difficulty is encountered with the expressions ${}^cR$, ${}^cA$, ${}^cW$. In Germany and Austria they stand for dimensionless or "absolute" coefficients, which are obtained by dividing the forces R, A, W by the area F and the pressure p, as given by the equations $R = {}^cR\,F\,p$, $A = {}^cA\,F\,p$, and $W = {}^cW\,F\,p$. To express these quantities as "unit forces" is better, it being generally easier to understand a mathematical formula when every factor stands for a definite and concrete entity rather than a purely philosophic concept. After all ${}^cR$, ${}^cA$, ${}^cW$ are "forces" in the accepted sense, for they express a weight in kilograms which would act on a one square meter of surface under a dynamic pressure of 1 millimeter hydrostatic pressure. To write with a small (^{c}) immediately conveys the impression that a *c*oefficient is expressed, and writing it *before* the symbol prevents misunderstanding with exponents. This method of writing instantly indicates what force the coefficient refers to and is therefore easier to read than either the English (k_L. k_D) the French (k_x, k_y) or the German (C_a, C_w) in all of which the stress is laid on the quantity as a "coefficient" and the force that it refers to is merely indicated by a small letter below. To avoid every mistake it should be noted that

$${}^cA = 200\ k_L = 1600\ k_y = C_a$$

In addition in Austria the following symbols have been accepted: ${}^sA$ for "specific lift" as per the expression $A = {}^sA p$ and ${}^rA$ for "reduced lift" as per the formula $A = {}^rA\ F$. These expressions have been found very useful. Of course the prefixes *s* and *r* have international significance in this respect.

THE BACKGROUND OF DETONATION

By STANWOOD W. SPARROW

A DETERMINATION of the relative merits of various fuels for use in high compression engines is the object of experiments being conducted at the Bureau of Standards for the National Advisory Committee of Aeronautics. Inasmuch as the tendency of a fuel to detonate often makes it unsuitable for such use, a consideration of the general subject of detonation has formed the initial step in this investigation. The purpose of this note is not to summarize the available information on the subject but to discuss a phase which seems to have received relatively little attention.

In most discussions of detonation attention has been focused on the rate or the nature of the combustion. Charge temperatures and pressures before combustion have been considered from the standpoint of their influence on this rate rather than from the standpoint of their influence on the temperatures and pressures after combustion. This does not imply that investigators have failed to appreciate this latter influence, but that they have thought of it as a sort of necessary background fixed by the compression ratio and so have turned their attention to a factor that could be altered, namely, the rate of combustion. It is believed, however, that a careful scrutiny of this "background" will throw considerable light on some of the results that have been obtained in detonation research and to this end the following discussion is devoted.

Fig. I, which presents results obtained from a one-cylinder engine, forms a convenient starting point. In this figure and throughout the paper, the presence or absence of detonation should be understood to mean the presence or absence of the metallic ringing sound characteristic of detonation.*

As indicated in the figure, detonation was only apparent at spark advances between 25° and 55° before center. More interesting is the fact that with this engine detonation only occurred when the explosion pressure as measured was somewhat greater than 450 pounds per square inch. From this, one would conclude that for a given engine the explosion pressure must exceed a definite value if detonation is to result. Such a conclusion is a natural consequence of the common belief that the sound which serves to identify detonation arises from a deflection or vibration of the combustion chamber walls. It seems logical, therefore, to consider such changes of engine condition as are known to affect detonation and to estimate the effect of such changes upon the explosion pressures.

Compression ratio deserves first attention as it is known to exert great influence upon the tendency of an engine to detonate. Accordingly, calculated explosion pressures for several compression ratios have been plotted in Fig. 2. These have been computed as though the entire charge were burned at top center with no heat loss. Obviously explosion pressures thus calculated should exceed those obtained in practice.

* For a discussion of quantitative methods of measuring detonation, see "Methods of Measuring Detonation in Engines," by Thomas Midgeley, Jr., and T. A. Boyd. Journal of the Society of Automotive Engineers, January, 1922.

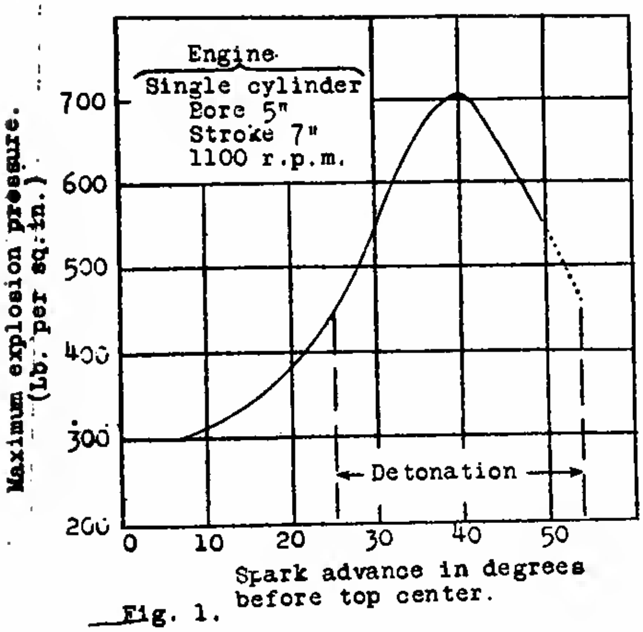

Fig. 1.

Nevertheless they form a satisfactory basis for comparison, provided actual rates of burning and heat dissipation are approximately the same for all the conditions compared. Moreover, ground for believing that this assumption is not far from the truth comes from the testimony of numerous investigators that they have obtained maximum power with nearly the same spark advances over a wide range of fuels* and compression ratios.

In calculating the values for Fig. 2, the following familiar relations have been employed:

$$P_2 = P_1 r^n$$
$$T_2 = T_1 r^{n-1}$$
$$M = T_3 - T_2$$
$$P_3 = P_2 \left(\frac{T_2 + M}{T_2} \right) = P_2 \left(1 + \frac{M}{T_2} \right)$$

where

r = ratio of compression and expansion.
P_1 = absolute pressure at beginning of compression stroke.
T_1 = absolute temperature at beginning of compression stroke.
P_2 = absolute pressure at end of compression stroke.
T_2 = absolute temperature at end of compression stroke.
M = increase in mixture temperature due to combustion.
T_3 = absolute temperature after combustion.
P_3 = absolute pressure after combustion.
n = exponent having experimental values ranging from 1.25 to 1.35.

In preparing Fig. 2, P_1 has been taken as 14.7 pounds per square inch, M as 2700°C and n as 1.3. In figuring T_1, the fresh charge has been assumed equal to the piston displacement in volume when at atmospheric pressure and at an absolute temperature of 320°C. In like manner the residual products of combustion have been assumed of a volume equal to the engine's clearance space when at atmospheric pressure and at an absolute temperature of 1273° C.** Some values thus calculated are tabulated below:

r	T_1	T_2	P_2	P_3	T_3
4	393°C	595°C	89	494	3295°C
5	376	610	119	645	3310
6	365	625	151	806	3325
7	358	643	185	960	3343
8	353	660	219	1115	3360

* All fuels give nearly the same maximum power at the same compression ratio.

** It should be remembered that the aim is a comparison rather than accurate determination of temperature and pressures. This justifies the omission of steps that otherwise would be essential. For example, the temperature increase produced by combustion has been taken as 2700°C for all compression ratios, although because of the smaller clearance volume of spent gas the amount of temperature rise should increase with the ratio (since less of the energy of combustion is expended in raising the temperature of the inert gas). An opposing tendency is the increase in specific heat that results from the higher compression temperatures of the higher compression ratios. The use of the same value of exhaust gas temperature for all ratios is open to similar

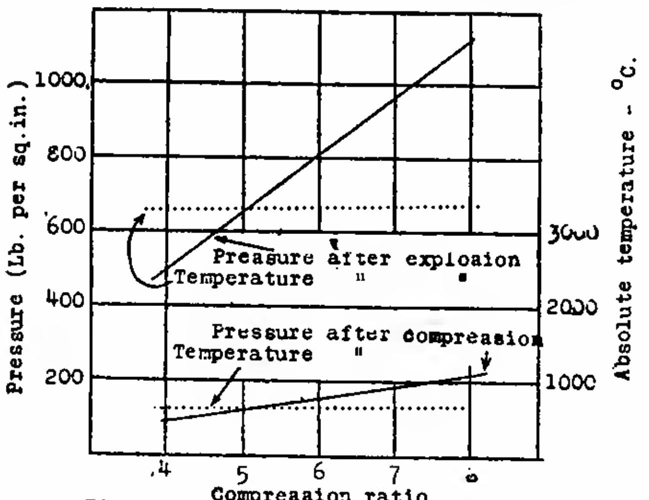

Fig. 2

Digitized by Google

criticism. An increase in expansion ratio tends to lower this temperature, which effect is opposed by a decrease in heat loss due to the decrease in combustion chamber surface. These various tendencies have been considered but are not included in the calculations as their combined influence should affect the comparative values less than 5%.

Attention has been directed repeatedly to the many tendencies toward an increase in combustion rate with an increase in compression ratio. A smaller volume through which the flame must spread and a smaller proportion of inert gas are two of the factors emphasized. All such tendencies would increase the differences shown in Fig 2. The significant thing is that, neglecting all such possibilities, assuming no change in combuston rate, there would still be an increase in explosion pressure of over 125% produced by changing from a ratio of 4 to one of 8. This change in ratio would only increase the absolute temperature at the end of compression by 11% and the absolute temperature at the end of combustion by 2%. One is not surprised, therefore, that a well known British investigator concludes charge temperature to be of minor importance from a detonation standpoint.*

At this point it is well to consider Fig. 3, which presents some of the most interesting information that this investigator, Mr. Ricardo, has obtained from his variable compression engine. The figure shows data obtained by throttling the engine, at compression ratios above 4.8, to the point of detonation. The dotted line shows the I. M. E. P. obtained at full throttle with a non-detonating fuel. After operating at each ratio the compression pressure was measured with a gauge while the engine was driven by a motor at the same speed and throttle opening as before. The most striking lesson from this curve is that detonation occurs at very nearly the same compression *pressure* regardless of the compression *ratio*.

Inasmuch as this discussion is concerned with the relation of explosion pressures to detonation, an estimate of the probable explosion pressures for the conditions shown in this figure is in order. One might anticipate that the expansion of the gases after passing the throttle would cause an appreciable temperature drop. Calculation and experiment both show this effect to be negligible under the circumstances under consideration.* Another factor which is likely to influence the temperature at the beginning of compression is the proportion of exhaust gas present. This can be estimated rather closely by assuming that the weight of fresh charge at part throttle bears the same relation to the weight of charge at full throttle as the I. M. E. P. at part throttle bears to the I. M. E. P. obtained at full throttle with a non-detonating fuel.

* Harry R. Ricardo, "Transactions of the January, 1922, Meeting of the Society of Automotive Engineers." The conclusion quoted is expressed thus, "Our experiments appeared to show pretty clearly that detonation has very little connection with the temperature of compression, but is closely dependent upon the compression pressure."

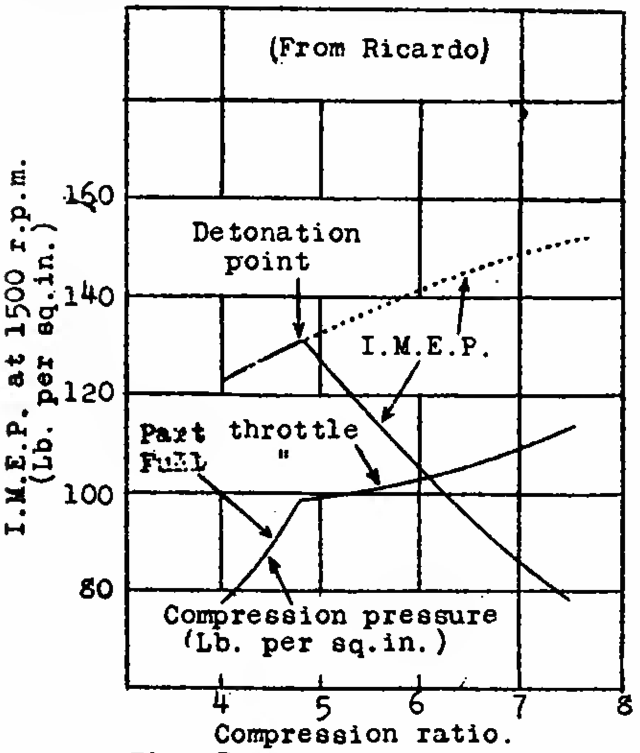

Fig. 3.

Actual experimental determinations of I. M. E. P. are given in the figure. Except for the use of the I. M. E. P. to estimate part throttle exhaust gas content, the method of calculation is the same as that used in obtaining Fig. 2. Although throttling an engine of fixed compression ratio tends to increase the proportion of exhaust gas to fresh charge, the calculations indicate that with the variable compression engine under the circumstances under discussion there is an accompanying decrease in clearance volume which neutralizes this effect. Thus over the range covered by the curves the exhaust gas expressed as a percentage of new charge varies less than 1. It follows that the temperature at the beginning of compression will remain nearly constant and values calculated on this basis are tabulated below:

r	T_1	T_2	T_3
4.8	388°C	620°C	3320°C
5.0	388	629	3329
5.5	388	648	3348
6.0	388	664	3364
6.5	388	680	3380
7.0	388	696	3396
7.5	388	710	3410

It will be recalled that the relation between explosion pressure and compression pressure is as follows: $\frac{P_3}{P_2} = 1 + \frac{M}{T_2}$.

An increase in compression ratio means an increase in T_2 and hence a decrease in the value of this ratio. For this reason a higher explosion pressure will be obtained from a low compression ratio engine at full throttl than from a high compression ratio engine throttled to the full load compression pressure of the low ratio. This fact may be stated from a slightly different angle in this fashion—to maintain a constant explosion pressure the compression pressure should increase slightly with increase in compression ratio.

* On p. 109, of Bulletin No. 19, of the Engineering Experiment Station of Ohio Stste University, Prof. Norman discusses the laws governing this drop in temperature and calculates the following values:

Gas velocity in feet per second	50	100	200	300
Temperature drop in degrees C	0.1	0.4	1.8	4.2

Tests at the Bureau of Standards showed no decrease in manifold temperature when the throttle of an aviation engine was closed while it was being motored with the fuel supply cut off.

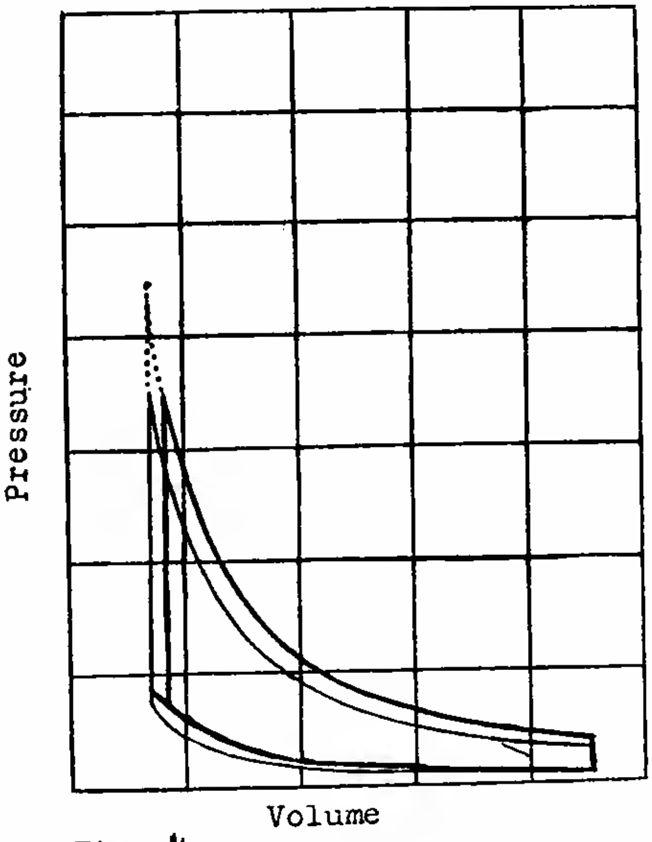

Fig. 4.

Digitized by Google

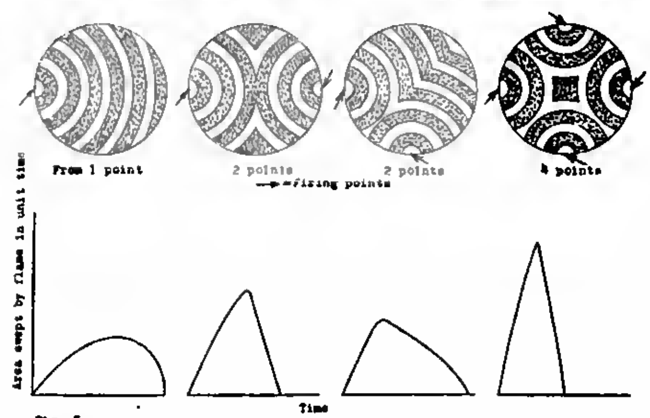

Fig. 5.

Explosion pressures as calculated for Fig. 3 are tabulated below:

r	P_2 (Absolute Pressure)	P_3
4.8	113	606
5.0	113.2	599
5.5	114.2	589
6.0	116.2	589
6.5	119.2	592
7.0	123.2	601
7.5	127.7	612

The maximum variation in explosion pressures is seen to be less than 4% and the deviation from the average pressure about 2%. When experiment has shown detonation to be constant under the conditions of Fig. 3, and calculations show explosion pressures to have been constant, there is reason for a deepening conviction in the close relationship of explosion pressures to detonation.*

Scavenging, that is to say, removing all or part of the spent gases from the clearance space, increases detonation. This fact has been taken as convincing proof of the great influence exerted by small proportions of exhaust gas on the rate of flame spread. Very probably this influence exists and operates as supposed. It is true, nevertheless, that the effect of scavenging on detonation can be explained partially at least by its influence on the explosion pressure. This influence is twofold. First of all, removing the hot exhaust gases from the clearance space of the engine means a lower temperature at the beginning and hence at the end of compression. Reverting again to the relation $\frac{P_3}{P_2} = 1 + \frac{M}{T_2}$, it is clear that lowering T_2, increases the ratio and thus the explosion pressure. This holds true if M, the increase in temperature resulting from combustion, does not decrease. But M should increase since the energy of the fuel is expended in heating a smaller mass of inert gas. This then is the second tendency toward increased explosion pressure and consequently detonation. Calculated explosion pressures show a probable increase of over 25% for a scavenged in comparison with an unscaveneged engine having a compression ratio of 4.

Another influence which vitally affects detonation is the ignition timing, the spark advance. As before, it is convenient to picture the charge burned at constant volume at a point in the stroke governed by the spark advance. This does not mean picturing the combustion as occurring at the same time as the spark but as always occurring at the same interval of time after the spark. The burning that takes place during this interval may be treated as the burning of a fuse that later fires the explosive. As shown when discussing the effect of compression ratio, the maximum explosion pressure should occur when the pressure prior to combustion is greatest. Since the charge is compressed most at top center the maximum explosion pressure should result from a spark so timed as to cause the actual combustion to take place at that part of the stroke and retarding the spark so that combustion comes later should decrease the explosion pressure. For the engine from which the pressure measurements of Fig. 1 were taken the estimated ratio of the explosion pressures obtained with combustion at various angles past top center to what would have resulted from combustion at top center are given below.

Degrees of crank angle after top center at which equivalent instantaneous combustion occurs.	Explosion pressure in % of the pressure when equivalent instantaneous combustion occurs at top center.
0	100
10	94
20	84
30	72
40	59
50	49

This demonstrates that very considerable differences in explosion pressure would be expected from a change in spark advance even if the rate of combustion remained the same. When there is superimposed the influence of a change in rate, it is not surprising to find differences of the magnitude shown in Fig. 1. The pressure at the time of explosion should be the same whether combustion takes place at a given angle before top center or after. With combustion before center, however, barring the heat loss, the subsequent compression of the burned gases will increase the pressure to a value in excess of that resulting from burning the charge at center. In practice it often happens that with an early spark the rate of heat loss exceeds the rate at which heat is produced by the compression of the burned charge so that the maximum pressure of the cycle is lower than with a less early spark. This accounts for the decreased pressures at the extreme spark advances of Fig. 1. Furthermore, it is not surprising that carbon-bisulphide, which preignites early in the stroke, does not detonate since the effect of preignition is that of a too early spark.*

The relative influence of spark advance and throttle opening on detonation is of considerable importance in connection with the use of high compression over-dimensioned engines. Such engines have too high a compression ratio to operate safely at sea level at full throttle with the spark advance that would give maximum power with a non-detonating fuel. Experiments at the Bureau have shown that for an emergency "take-off" such engines will develop more power if the spark is retarded to eliminate detonation than if the throttle is closed to produce the same effect.

Aside from its practical bearing on engine design, it is worth while to see whether the comparative influence of spark advance and throttle opening would be predicted from their influence on explosion pressures. The theoretical indicator cards of Fig. 4 will aid the comparison. In this figure the dotted line indicates the pressures at full throttle with a non-detonating fuel and a compression ratio of 6.5. The problem is to obtain from this engine the maximum power that is possible with a fuel which because of detonation cannot be used with an unthrottled engine having a compression ratio in excess of 5.5 (the volumetric efficiency is assumed the same for both ratios). If explosion pressure controls detonation, the problem resolves itself into so adjusting spark advance or throttle as to restrict the explosion pressure to the value obtained with an unthrottled engine of 5.5 ratio. Since the explosion pressure with a 5.5 ratio is about 82% of that with a 6.5 ratio, an engine having the latter ratio must be throttled to about 82% of full load. (Taking into consideration the modifying factors discussed in connection with Fig. 3, gives 85% as a closer value.) The full curve of the figure shows the probable pressure under this throttled condition.

The other alternative is to retard the spark so that combustion does not take place until the piston has traveled far enough on the down stroke for the pressure to have fallen to the maximum compression pressure with the 5.5 ratio. A full heavy line shows the pressures under this condition. Since the engine receives a full weight of charge, the power should be less than that obtained with the non-detonating fuel only because the ratio of expansion after combustion is 5.5 in contrast with 6.5 with the non-detonating fuel and the optimum spark advance. The air cycle efficiency** for a 5.5 ratio is 94% of that for a 6.5 ratio. Thus retarding the spark to

* On page 6 of "Recent Internal Combustion Engine Research," presented at the January, 1922, meeting of the Society of Automotive Engineers, Mr. Ricardo says: ". . . the tendency to detonate depends in effect upon the compression pressure not, as I supposed, because the pressure has any marked influence, but rather because in any actual engine the compression pressure is in itself a measure of the proportion of inert diluent present in the cylinder."

The reader will perceive that the author's interpretation of the data is somewhat at variance with Mr. Ricardo's. It is regrettable that the scope of the paper does not permit citing the many views of Mr. Ricardo with which he is in hearty accord. The use of Fig. 3 is but one indication of his belief in the accuracy and value of Mr. Ricardo's experimental determinations.

* In the Journal of the Society of Automotive Engineers, September, 1920, C. F. Kettering says: "Using carbon-bisulphide as a fuel, we get a genuine preignition. This fuel ignites very early and the pressure rises rapidly but it will not knock. Preignition will not necessarily cause a knock, because it may be that the pressures will not rise higher than normal."

** Air cycle efficiency $= 1 - \frac{1}{r^{n-1}}$ where n = 1.4 and r = expansion ratio.

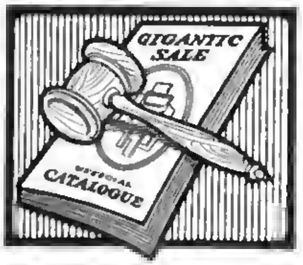
About the SELLING METHODS of the War Department

AUCTION



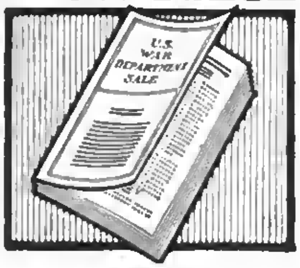
THE BENEFITS OF AUCTION SALES

1. Purchase is so easy. You simply raise a numbered paddle, so the auctioneer sees it. The paddle costs about $200, which is applied to your purchases. If you do not buy, the deposit is returned in full, on demand.
2. The offerings usually MUST he sold. This gives you opportunity to huy right.
3. Your competitor's hid furnishes a guide to the value of the goods offered.

WHAT SEALED BID OFFERINGS GIVE

1. More time for financing purchases.
2. Quality that stands up in any market.
3. Quantities worth your while.
4. Opportunity to huy what you need at prices you set yourself.

FIXED PRICE



HOW THE FIXED PRICE HELPS YOU

1. It gives your dime the same opportunity to huy value that is afforded your neighhor's dollar. The price is the same to all, whether you huy one item or ten thousand.
2. It simplifies purchases. You get a catalog, check up your needs, decide what you want to spend, and then send in your order. That's all.

For further information regarding War Department Sales, write:

MAJOR J. L. FRINK,
Chief, Sales Promotion Section,
Office of Director of Sales,
Room 2515 - Munitions Building,
Washington, D. C.

avoid detonation requires a 6% decrease in power against the 15% sacrifice which throttling entails.

From all the evidence presented it appears that a close relationship exists between explosion pressures and detonation and that, having calculated the explosion pressures for an engine condition at which detonation occurs, for any other engine condition the probable presence or absence of detonation can be predicted from a calculation of the probable explosion pressure. It does not follow necessarily that the uniform explosion pressures as here calculated produce the sound of detonation. There is evidence that there are local pressures which exceed these average pressures and to which should be charged both the sound and destructive effects of detonation. The evidence does indicate that if local high pressures exist they are proportional to the average pressures as calculated, inasmuch as the latter have proved an accurate index of the presence or absence of detonation.

Emphasis, thus far, has been placed on conditions that influence detonations even with the rate of combustion unchanged. Better appreciated and no less important is the influence of a change in combustion rate with other conditions remaining constant. In fact, detonation research has confined itself largely to attempts to influence this rate. The goal is a slowing down of the final stages of combustion. It may be neither necessary nor desirable to decrease the average combustion rate. Tradition tells us that it was the "*last* straw" that brought disaster to the back of a camel and similarly, it is the *last* rise in pressure that brings ruin to the head of a piston. An illustration will show how this disastrous peak pressure may be avoided by a slight change in the combustion rate. For the first condition assume that the piston is at top center, that all the charge has been burned and that the charge temperature is 3350°C. Assume also that a temperature drop of 250°C results from the heat dissipation during the next 10° of crank motion. For the second condition let it be assumed that when the piston reaches top center sufficient charge has been burned to have produced a temperature of (3350 — 250)°C and that the remainder is burned during the next ten degrees of crank motion at such a rate that the heat input shall just offset the heat dissipation and the pressure and temperature at 10° past top center be approximately the same as in the first case. The ratio of the pressure in the latter case to that in the former is $\dfrac{3350 - 250}{3350}$ or 93%. The only difference in power that should result is that due to a loss in efficiency chargeable to the decreased expansion ratio of the portion of the charge burned in the ten degrees after center. Calculation shows the net loss to be less than two-tenths of one percent. In short, a decrease of 7% in maximum pressure is obtained at the expense of a decrease of two-tenths of one percent in power.

Fig. 5 indicates in a general way why differences in spark plug position and combustion chamber shape change the rate at which the charge is consumed. By means of the alternate light and dark areas the amount of surface swept by the flame from each spark plug in equal time intervals can be determined. The lower plots show total areas swept by flame in unit time plotted against time. In these figures the area under the curve at the left of any ordinate represents the total area swept by the flame up to that time. The upper flame spread diagrams are drawn as though the flame moved radially at a uniform linear rate. This assumption is admittedly false for the flame, at least in its initial stages, spreads at an accelerated rate. Moreover, in the engine it is not areas with which one is concerned but volumes and the problem is further complicated by the movement of one wall of the combustion chamber, namely, the piston head. Obviously, then there is no point in analyzing the figures to show which spark plug arrangement gives minimum detonation. Their sole aim is to show why a change in spark plug arrangement should make a difference in detonation.*

A discussion of the influence of changes in fuel characteristics upon detonation lies outside the province of this paper. Possibly the most hope of relief from detonation troubles lies in the ability to alter these characteristics, and much excellent work has been done in this field.**

Except in the case of the automobile engine the noise of detonation in itself is of no consequence. Detonation's seriousness lies in its high pressures and in the excessive heat loss which prevents the attainment of the power that would otherwise be possible. Most investigators have been made acquainted with this excessive heat dissipation by an increased loss to the jacket water whenever detonation has been present. In a preceding paragraph a comparison was made between the effect of burning all the charge at top center with a resultant temperature of 3350° C. and slightly retarding the rate of burning so that the maximum temperature did not exceed 3100° C. Radiation varies approximately as the fourth power of the absolute temperature and would at top center be 35% greater with the higher temperature. It seems clear that much of the power loss that accompanies detonation can be attributed to excessive heat dissipation arising from a condition approximating the one just mentioned.

Preignition and detonation are now generally conceded to be entirely independent phenomena. Preignition is unusual, caused by a hot spark plug electrode, by an exhaust valve or by a piston head and depends upon the ignition temperature of the fuel. Changes in the design of these members will do much to prevent this trouble. The important fact is that such changes will be necessary with an increase in compression ratio unless the fuel has been prepared to eliminate preignition as well as detonation. It may be mentioned in passing that overheating troubles are a more likely result of preignition than of detonation. This can be illustrated best by assuming an extreme case of preignition with the charge ignited as it enters the cylinder and all burned by the beginning of the compression stroke. It is conceivable that the rate of heat dissipation during this stroke should be such that at top center the same pressure and temperature would result as when, under normal operation, the bulk of the charge is burned at top center. Pressures and temperatures during expansion would be the same for both cases. For the compression stroke, however, the average temperature with preignition would have been in the neighborhood of 3000° C. in contrast with 500 °C. under normal operation.

As stated in the outset, this paper's sim has not been to present a complete picture of detonation but to consider several more or less independent features of the problem which have received comparatively little attention. Whether these features belong in the backgeound or foreground is immaterial so long as they are recognized as an essential part of the picture.

---

* For a discussion of actual combustion chamber shapes and their influence upon detonation, see "Turbulence," by H. L. Horning, on page 579 of the Journal of the Society of Automotive Engineers, June, 1921.

** "Combustion of Fuels in Internal Combustion Engines," by C. F. Kettering, Journal of the Society of Automotive Engineers, September, 1920; "Combustion of Fuels in Internal Combustion Engines," by Thomas Midgely, Jr., Journal of the Society of Automotive Engineers, December, 1920.

(*Concluded from page* 200)

The symbol *e* to indicate the distance of the center of pressure from the upper aerofoil surface has been in use in Germany and Austria for over ten years with good results. In other countries this quantity is seldom made use of. Whether *e* is the best symbol for this expression is a matter that should be decided by the committee.

M as an expression for torque is a well known symbol in mechanics, and it is advisable to retain it for that reason. Mathematically $M = N \times e$ and since N is nearly equal to A the expression $M = A \times e$ can be safely used for approximations. In Austria the special symbol ${}^{a}M = A \times e$ has been adopted.

Just as we have units of force we can have a "unit of torque"—also an abstract coefficient. For its expression ${}^{c}M$ has been devised with its corollary ${}^{ca}M$. We can, therefore, write

$$M = {}^{c}M \times F \times p \times t \text{ and } {}^{a}M = {}^{ca}M \times F \times p \times t$$

in which "t" is the chord.

Σ expresses in Germany the ratio $\dfrac{W}{A}$ and χ the angle of incidence. Whether these symbols should be internationalized is fit subject for discussion.

Regarding the graphic representation of test results it may be observed that the Vienna laboratory conforms itself to the standards prevalent throughout Germany.

It would be very desirable to come to some international agreement regarding the unification and standardization of aerodynamical expressions, and we hope that Mr. Knight will succeed in eliminating such objections as still, perhaps, exist toward the satisfactory solution of this important matter.

Translator's Note—In his paper Dr. Katzmay speaks of $\Sigma \dfrac{W}{W}$ as indicating, that is $\dfrac{\text{drift}}{\text{lift}}$. I have retained this expression in the translation in spite of the apparent error. In Germany the lift drift relation is expressed as a fraction. Here is a matter which surely calls for standardization.

I cannot agree with the author that "shear" would be preferable to "lift". There is nothing in the latter word that presupposes (as he states) a direction opposed to gravity and a *lifting* force might easily be conceived acting at an angle to the absolute vertical. In an aeroplane "lift" resolves itself into a "shear" at wing hinges where the latter are fastened to the fuselage, but that is a mechanical condition which is no factor in wind-tunnel work.

NAVAL and MILITARY AERONAUTICS

New Airship Class at Langley Field

Due to the fact that the last Airship Class at Langley Field, Va., was nearly wiped out as a result of the Roma tragedy, the next class is being pushed forward, and it is now expected that it will commence operations on April 24th. This class will be composed of ten officers. Every effort is being made to supply the present deficiency of airship pilots so that the tactical development of airships may be proceeded with.

The Fastest Airship in the United States

The loss of the "Roma" created quite a void in the big lighter-than-air hangar at Langley Field, Va., and, to compensate for the loss of the giant dirigible, an English "Mullion" type airship was inflated about three weeks ago and has since been operated quite extensively. It is being used for the training of cadets in the piloting of two-man control airships.

The "Mullion" type airship was developed by the British in 1918 for use as a short range coastal patrol ship. It is fitted with two 75 h. p. Rolls-Royce "Hawk" engines, mounted above the stem of a streamlined car and driving pusher screws. The envelope has a capacity of 100,000 cubic feet of buoyant gas, and measures 165 feet in length, 49 feet in height and 35 feet, 6 inches in diameter. While the theoretical full cruising speed is 57.5 miles per hour, the airship officers who have flown this ship at Langley Field state that it is the fastest airship in the United States today. On several occasions it is claimed that a speed in excess of 61 miles per hour has been achieved.

This ship is very trim and neat in appearance, and offers considerably less resistance to the wind on account of the construction of suspensions, and the shape of the bag itself. It has the customary two ballonets and trims very nicely. It is reported, however, that the directional controls do not function as decisively and promptly as would be desirable. This is no doubt due to the fact that there is no top tail surface. All directional stability is taken care of by a lower tail surface to which the rudder is attached, and this results in a slight amount of rolling. On altitude control this ship behaves excellently and promptly. The car is light and well designed. Four or five passengers can be carried, although she functions better with only four passengers.

Shortly after the Armistice the War Department purchased several of this type of airship. The first one was inflated at Langley Field in 1919, but was destroyed when the temporary hangar blew down. Since that time A, C and D type of ships have been operated for experimental purposes, and this is the first time a "Mullion" has been put in the air.

The "Mullion" is also called the "S. S. T.," which stands for "Submarine Scout Twin," being motored with two engines. This type of airship performed flights of considerable duration for the British Navy and were used for locating and bombing of submarines. Quite a few German submarines were destroyed through the agency of this airship.

Flying Cadets Complete Training

The entire class of flying cadets assigned to Mather Field, Mills, Calif., completed their flying training and will receive commissions in the Reserve Corps, viz:

James C. Ayers, Walter A. Archer, John M. Barnes, Donald M. Cornell, Paul M. Conner, Robert J. Clohecy, John R. Rand, Sidney C. DuBose, Clarence A. Gilbert, Lloyd L. Hefling, Clinton E. Herherger, Guy F. Hix, Theodore R. Howe, Max M. Sternberg, Iver Igelsrud, Andrew J. Marincik, Ive McKinney, John C. McGinn, Leo L. Mellon, Earl C. Pierce, Arthur L. Smith, Donald A. Templeman.

Of this class, Cadets Hefling, Igelsrud and Ayers took the examination for appointment as 2nd Lieutenants, Regular Army, at the Presidio of San Francisco. The results of their examinations have not yet been determined. By their behavior and application during their training they have each proven that they would be the sort of officers needed in the Air Service.

A Lecture on Meteorology

The command at Mather Field, Mills, Calif., was treated to an interesting lecture on forecasting, meteorology, aviation and sundry subjects, delivered by Mr. Thomas R. Reed, of the San Francisco Weather Bureau. Mr. Reed's work in meteorology has been wide and varied. Added to this knowledge is his experience as an aviator with the French and American forces during the war, making him an authority on the subject as applied to flying particularly. His talk was of absorbing interest to his audience, and the information gained will be of great assistance to each flyer.

Fast Time Between Kelly and Ellington Fields

A report from Ellington Field, Houston, Texas, is to the effect that, so far as known, the fastest cross-country flight between Ellington Field and Kelly Field was made by Lieut R. T. Aldworth in an MB3 on April 1st. The duration of the flight westward was one hour and 23 minutes (151 8 m. p. h.) while the return flight against a somewhat higher wind was made in one hour and fifty minutes (114.5 m. p. h.) The distance between these two stations is 210 miles.

Spads and MB3's at Ellington Field

The 1st Group (Pursuit) at Ellington Field is rapidly being equipped with Spad and MB3 planes. It is planned by the 15th of April to have enough MB3's assigned to the squadrons to equip each officer of the Group with a plane in preparation for the forthcoming annual tactical training operations to be conducted during the latter part of June.

Ready to Tackle Forestry Patrol

In the event Forestry patrol is authorized for this season, there is not a man in the 91st Squadron at Crissy Field who will not be eager for this duty—which, by the way, is not strange, considering their phenomenal ability to make "smokes" disappear. The Squadron's radio department will be ready. Eight enlisted men have been enrolled in the Signal Corps Radio School being conducted at the Presidio, where they will receive a thorough course in operation and maintenance of radio. Two experienced radio operators are now on duty with the Post Radio Department, and the ships of the 91st are rapidly being equipped with newly overhauled equipment. The pilots and observers are receiving practical instruction by being required to work with the home station while on flights.

A New Hospital Aeroplane

The JN6HG aeroplane, which was remodeled at the Fairfield, O., Air Intermediate Depot into a hospital ship, has been completed and, as soon as weather conditions permit, it will be flight tested. From all reports, this is the first aeroplane of this type that has ever been manufactured. A special litter, constructed in the fuselage and easily accessible by swinging lids, makes a very desirable aeroplane for the purpose of transporting injured persons. The physican or attendant is provided with a cockpit immediately in front of the litter and just back of the pilot's cockpit facing the tail surfaces. It is so situated that at all times the physician or attendant is able to observe the patient through a window which is cut in the fuselage. This type of ambulance aeroplane is a decided step forward in transporting injured persons by aeroplane.

Crissy Field Notes

On March 27th Master Sergeant William F. Hohorst and his seven "go-getters" returned to Crissy Field from their two weeks' recruiting trip, which has carried them through Healdsburg, Santa Rosa and Petaluma, at which latter place they established recruiting headquarters. Seven recruits have been added to the ranks of the Air Service as a result of this trip, and Sergeant Hohorst reports that were it not for the lack of transportation funds, this number could have been more than doubled. The eager interest and keen desire to join the Air Service manifested by the majority of prospective recruits approached by the men from Crissy Field, wavered, waned and finally resolved into inaction because of the lack of the necessary supply of "filthy lucre" to transport them to Crissy Field.

The national magnet at the present time seems to be Radio, which is rapidly drawing all men unto it. In its efforts to meet the demands of the thousands of radio "fans" in the Bay district, the University of California Extension Division requested the co-operation of Crissy Field, with the result that on Friday of last week Mr. Allen Smith, an Air Service Reserve Officer, who is at present connected with the University of California, announced from a Crissy Field ship in which was installed an SCR-68 telephone set, a course of lectures on radio to be delivered in San Francisco by Mr. Herbert E. M. Metcalf, a radio expert, formerly connected with the Air Service. Judging from the enthusiastic attendance at Mr. Metcalf's lectures, Mr. Smith's announcement was a "sho' nuf" "heavenly" message.

FOREIGN NEWS

London Papers on Paris Breakfast Table

With this week most of the London papers will be carried by air and will be available in Paris between 9 and 10 a. m., under arrangements made by Messrs. Hachette. Excellent!

Air Mail to Denmark

We understand that arrangements have been made for inaugurating, this month, an air mail service between Rotterdam and Copenhagen. The company which is to undertake the new service is stated to be Danish, although it is intended to use British machines and pilots. The plan is to have machines leaving Rotterdam in the morning, after the arrival of the night boat from London, and it is expected that they will be able to reach Copenhagen shortly after noon, so that the mails should be distributed early in the afternoon in Copenhagen. In the opposite direction machines will leave Copenhagen at 3 p. m., and will reach Rotterdam in time to connect with the night boat to London. Thus, instead of taking 72 hours, the mails between London and Copenhagen should do the journey in about 24 hours.

New British Empire Air Service Plan

Very considerable interest has been aroused by the announcement of the scheme for the formation of a company to establish an airship mail and passenger service to India and Australia. At the moment of writing, the decision of the Air Council in the mtater has not been made public, consequently it is not known whether this scheme, which calls for no capital investment by the Government, but only a contingent liability in the form of a State guarantee of interest of £91,000 per annum, will mature. The proposal has the backing of Vickers, Ltd., and of the Shell group, and the details of the scheme were explained at a private meeting at Caxton Hall, on March 30, by Commander C. Dennis Burney. Mr. A. H. Ashbolt, Agent-General for Tasmania, who has long been one of the stoutest advocates of Imperial airship services, presided, and Major G. H. Scott explained certain technical considerations. If the scheme meets with Government approval, it will presumably mean that existing airships will not be handed over to the Disposals Board.

Briefly, the scheme submitted by Commander Burney to the Air Ministry is as follows: The company's capital of £4,000,000 would be made up of £1,800,000 in ordinary shares, and £2,200,000 in debentures, subject to the Government arranging, by means of a subsidy, a guarantee of dividend and interest for a period of years. On ordinary shares a 6 per cent. dividend (free of income-tax) would be guaranteed for 10 years, and the debentures would carry 4½ per cent. interest (free of income-tax) until redemption. It is proposed that £1,200,000 ordinary shares and £2,200,000 debentures should be issued forthwith, leaving £600,000 ordinary shares unissued.

Of this share capital, Messrs. Vickers, Ltd., have undertaken to subscribe for 100,000 shares at par and the Shell group for 100,000 ordinary shares or debentures at par. Both companies will give full technical assistance. It is stipulated that the Government shall transfer to the company free of all airships, airship material, and airship bases—such as Pulham, Cardington, and Howden, and will supply wireless telegraphy and meteorological services.

The total contingent subsidy per annum in the form of a guarantee of dividend on the ordinary shares and interest on the debentures (on the capital now proposed to be issued) would be:—On £1,200,000 ordinary shares, £72,000 for 10 years; on £2,200,000 debentures, £99,000 until redemption, divided as follows:—British, £91,000 per annum; Australia, £40,000; and India, £40,000. These dividend and interest payments would cease as soon as the profits from the company were sufficient to pay them. It is suggested that no dividend or interest should be payable until the middle of 1923, and accordingly the coming Budgets will be unaffected. ?

The program of development would be divided into two stages—(a) a bi-weekly service to India; (b) an alternate day service to India, with a weekly extension to Australia. Capital would thus be conserved until the necessary experience has been obtained, to render the service efficient on the first stage, before expanding to the second stage. Commander Dennis Burney asks that until time has been given for consideration of this offer no airship or airship material should be broken up or otherwise disposed.

It is estimated that, unless the public take to airship travel very rapidly, there will be a loss on running expenses for the first two years. During this period nothing will be earned to write off depreciation charges, but, on the other hand, experience will give rise to large improvements in the design of airships, and consequently the airships originally constructed by the company will become obsolete with more than normal rapidity. The cost of this will be about £750,000, and it is suggested that when the profits have reached such a figure as to relieve the Government from their guarantee of dividend upon the ordinary shares, and the company can show to the satisfaction of the Treasury that it has established the business on a commercial basis, the Government will refund to the company the £750,000.

Estimates of expenditure and revenue were also submitted. They provide for the building of five new airships (the present fleet will be used for training and for short journeys only). The new ships will be much on the lines of the "LZ125," so far as size is concerned, with a capacity of 3,800,000 cubic ft. On a bi-weekly service to India it is believed that there would be a return of £372,000 per annum, after paying all costs and depreciation charges. Details were also given of a proposed extension to Australia. The sum available for ordinary shares is estimated at £240,000 per annum.

For the first year of full service it has been assumed that receipts will only equal one-third of the running costs, or £130,000 as against a total earning capacity of £1,482,200, and for the second year total receipts of £260,000. It has been further assumed in the computation of dividends that when the service is in full working order yearly earning of £1,037,000, against the total of £1,482,200, will be obtained.

The airships to be used would have a maximum speed of 70 knots, and it is thought that an average speed of 55 knots could be maintained. It is proposed to establish bases with mooring masts *en route*, and allowing six hours at each, the following time-table is estimated:

Bombay	5½ days	(now 17 days).
Rangoon	7½ "	(now 21 to 22 days).
Hong-Kong ...	8½ "	(now 4 to 5 weeks).
Australia	11½ "	(now 4 to 5 weeks).

To Advertise Air Travelling

A new scheme has been devised by the Lep Aerial Travel Bureau to display to prospective London air passengers the advantages of travelling to the Continent by air. A small daylight cinema of a new type has been erected in the bureau in Piccadilly Circus, and films depicting the Customs examination, start from the aerodrome, scens *en route*, etc.. etc., are shown. while an official explains the film and points out the benefits to be obtained by using the newest method of travel.

Commercial Aviation in Germany

At least ten aviation companies are operating lines in Germany, says Economist Consul Parmelee, Berlin, in a report to the Department of Commerce. The 1921 returns of seven of these (data for the others not being available) show a total of 1,653,053 kilometers or 1,033,158 miles of flight, the transportation of 6,182 passengers, and 30,713 metric tons of mail and baggage. One company, the Deutsche Luft-Reederei, carried almost half of the passengers and three-fifths of the mail and baggage in flights totalling 346,826 miles.

The Deutsche Luft-Reederei has announced new routes to be opened to Prague in Czechoslovakia and to Moscow by way of Koenigsberg and Wytebok.

The German Government grants a mail subsidy of 10 marks per kilometer on routes up to 300 kilometers and 11 marks for routes above 300 kilometers, provided time tables are strictly adhered to, and provided mail up to 100 kilograms per flight is conveyed free of charge. Payment is provided for overweight.

Companies are entitled to subsidy if they can prove a minimum record of 20,000 kilometers within a year. Payment of the total subsidy is dependent on at least 80 per cent. punctuality per month. Ten per cent is deducted for each 5 per cent. loss of punctuality. After April 1, 1922, only those companies are entitled to a subsidy who can prove that for every three military machines used they have purchased one of modern type.

As the subsidy is limited, the regular postal air traffic is to be suspended or limited from November 1 to March 31.

Owing partly to weather conditions, it has not yet been attempted to operate regular services the year round. The cessation during the winter months is said to be due, in part, also, to the necessity of repairing the limited number of aeroplanes which have so far been available.

Article 202 of the Versailles Treaty and the subsequent London Ultimatum of May 5, 1921, have prohibited Germany either from manufacturing or importing aircraft. The note of February 1, 1922, however, has set May 5, 1922, as the date upon which resumption of construction, import and export of civil aircraft accessories will be permitted. Allied supervision of civil aviation in Germany will continue after May 5, 1922, though the precise form which this supervision will take is not yet known.

Pretoria Experiment

The Meteorological Office at Pretoria is about to liberate balloons to which instruments for determining the temperature and pressure of the air at various heights are attached. The balloon is quite free. It ascends until it bursts and then acts as a parachute to the falling instrument which is secured to a "spider" constructed of three springs of bamboo about 3 feet 6 inches in length. At the six ends of the bamboo small red flags are attached and the spider is so arranged that, however it falls, three flags lie well above the ground to attract the attention of anyone passing in the vicinity. The success of the experiment depends on the recovery of the instrument and the Government offers a reward of £1 to the finder, provided he carries out the instructions on the label attached to it. The label reads: "Investigation of Upper Air. This instrument is a delicate meteorological apparatus. Pull out the piece of red string with match end attached and then convey carefully to nearest Magistrate. If the instrument has not been tampered with you will receive £1 reward."

Rome-Tripoli Service

To establish more rapid communications between Italy and Tripolitania, the Secretary of the Colonies, Hon. Girardini, is endeavoring to organize an aerial mail service from Rome to Tripoli that may eventually be used also for the transportation of passengers. For this purpose the Superior Command of Aeronautics has granted the use of the airship Esperia (ex-Bodensee) to make its first flight, which will take place in the coming Spring. In the meantime, while they are completing certain works in order to prepare the aeroplane for her flight, her commandant, Major Valle, will go to Tripoli personally to make sure of a safe landing.

Palestine-Mesopotamia

The Palestine General Post Office has just announced the inauguration of a fortnightly mail service by aeroplane from Palestine to Mesopotamia, according to a report received by the Department of Commerce from Consul Southard at Jerusalem. There has been a military service over this route for some time, from Cairo via Palestine and Transjordania. This announcement merely opens the service to the public.

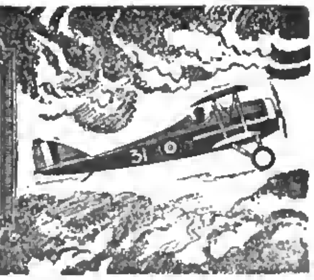
ELEMENTARY AERONAUTICS *and* MODEL NOTES



Elementary Aeronautics

Construction of the Navy Racer Model Trophy

BUILDERS of scale aeroplane models will be interested in the construction details of the miniature Curtiss-Navy model, recently presented to the Navy Department as a gift trophy by the Curtiss Aeroplane & Motor Corporation. The Curtiss Company designed and built the racing aeroplane in which Bert Acosta won the Pulitzer Trophy race at Omaha, on November 3d, last year. The successful flights of this plane created much enthusiasm among the naval officers responsible for its adoption by the Navy, and as a souvenir of the Omaha victory, the Curtiss Company had a special scale model constructed by its expert model builder.

Although many of the newspapers gave an account of the presentation, praising the fine appearance of the model, no mention was made of the actual construction and such information as desired by model builders. A representative of the Elementary Aeronautics page of AERIAL AGE interviewed the model expert who constructed the trophy, with the result that much intimate information was obtained concerning it.

All parts of the model were made and assembled by Mr. Thomas H. Birmingham, who is in charge of the Curtiss wind-tunnel model department. Mr. Birmingham has had considerable experience in building accurate scale models of steamships costing thousands of dollars. In the construction of model aeroplanes, whether for wind-tunnel tests or for display, he is able to carry out all the processes required for a model complete in every respect. For example, many model builders excel in wood-work, metal-work or finishing details, but it is unusual to find one whose work testifies his skill in all these branches, while at the same time forming a model so accurately to scale.

In designing this trophy model it was desired to keep the wing span close to ten inches. To accomplish this, all the measurements of the large machine were scaled down to 7-16ths of an inch to the foot. The outline of the model is accurately to scale within about 1-1,000th of an inch, which is extremely fine work for a model of this kind. Altho this is accurate, the regular scale models made by Mr. Birmingham are even closer to the exact scale measurements, being within 1-4,000ths of the precise figures reduced in scale. Wind-tunnel work requires such accuracy, for the slightest variation in true scale would make the tunnel tests of doubtful value.

Of course in such models no attempt is made to reproduce the weights to scale, and each part is formed of materials most suitable for forming the correct outlines. Solid silver was used wherever possible. The wings, which have the appearance of silver, were made of aluminum. The forming of these wings to the correct profile was a difficult job, requiring more than a week of work by hand.

The two N struts are of silver. At each end a small pin was left to project into the wing for fastening.

Tail surfaces are of aluminum, formed by hand filing. Braces to the fin and stabilizer, which on the real aeroplane are of steel, streamline wire are represented by fine silver wires on the model. Brace wires between the wings and on the undercarriage arc also simulated by silver wires.

Undercarriage V struts and axle streamline are of silver. The wheels were turned out on a lathe; the material used was brass, silver-plated. Tires were represented by a coating of heavy gray enamel.

The body was made of hardwood. It was divided into halves vertically through the centerline, and the portion at the pilot's cockpit hollowed out. A miniature instrument-board, seat and windshield are installed. The body is finished with four coats of gray coach varnish.

The two "Lamblin" radiators, located on the chassis struts, below the lower wing, proved to be the most difficult part to make. The real radiators themselves are of a complicated manufacture, and in reducing the parts in size, the complications were multiplied in proportion. Special moulds and dies were made to form the radiator shell, and the basket-like radiator tubes of silver-wire were arranged in their correct order by means of elaborate jigs.

At the rear of the body the steel leaf-spring tail skid is neatly arranged as on the real machine, with small overlapping spring leaves.

The base of the trophy is of turned ebony, polished. The pedestal shaft supporting the model is of silver, lathe-turned. A solid silver nameplate at the base is engraved with an inscription commemorating the winning flight of the Curtiss-Navy Racer, and bears the record of its speed over a "closed circuit" of 150 miles, which was covered in 52 minutes, 9 3-5 seconds, or at a speed averaging 176.7 miles an hour.

Insignias on the wings and rudder are of baked enamel, each color applied directly to the surface.

The propeller is made of maple, the grain of which, reduced at this scale, is in good proportion to the grain of oak, as used on the full-size machine. It is formed and finished with all the care and exactitude of real propellers.

A month of time was required to build the model and its actual construction cost was about four hundred dollars.

The Flight Association of Ottawa, Canada, Organized

Mr. Oswald Barry announces the organization of a new club, formed for the purpose of model experimentation. The club has been named The Flight Association of Ottawa, Canada, and Mr. Barry is its president, pro tem.

The Association is composed of willing workers, and the constitution is so drafted as to exclude those who are not seriously interested in model building. Some of the members are quite proficient in the work, having followed the model game for eight years.

A cordial invitation to membership is extended to all those residing in that section of Canada, and the earnest tyro is quite as welcome as the seasoned veteran.

Correspondence is invited from other clubs and from individual model builders. Mr. Barry's address is 117 Albert Street, Ottawa, Canada.

The Curtiss-Navy Racer Model presented as a souvenir to the Navy Department to commemorate the winning of the Pulitzer Race

RADIO DIGEST

10,000 Radio Fans Hear Bride's Kiss in Aerial Wedding

A kiss struggled through the ether April 24 and 10,000 radio enthusiasts knew then that somewhere between Mineola, L. I., and Forty-second Street and Broadway, New York, 2,500 feet up in the air, Miss Sarah Cockefair and Albert P. Schlafke had been safely married.

Miss Cockefair, who is a nurse in Brooklyn Hospital, and Mr. Schlafke, who is physical director of the Veterans' Camp at Tupper Lake, decided that since they were going to be married anyway they might as well have as large an audience as possible.

A six-passenger Fokker was rigged up with a radio set. Bert Acosta agreed to pilot the ship. The Rev. Belvin Maynard, the "Flying Parson," was there to perform the ceremony. So the wedding party hopped off with Frank Daniels to attend to the radio, seven-year-old Louise Robb, winner of sixteen baby shows, as flower girl and George Weed to see that everything went properly.

The bride threw out her bridal bouquet of roses when she was 1,500 feet up and, when the plane was passing over College Point Lieutenant Maynard began the service. His questions and the responses could be heard plainly from an amplifier set up on the field and by all those who were listening in on their own radio sets.

The couple landed at 5:40 in a shower of rice.

Radio Equipment of the Ships "Paris" and "Lafayette"

Is described in a recent issue of *Radio-electricite*. On both steamess a 5-kilowatt tube transmitter has been installed with a wave range of between 2000 and 9000 meters. A 5-killowatt motor-generator set is used to produce the plate high tension for four rectifying and four oscillatory tubes, and the low-voltage current for the heating of the filament of these tubes. Both vessels are equipped with a radio rangefinder, or "radio goniometer," which, reduced to plain English, means a radio compass. A distance of 3400 kilometers has been covered safely by messages sent from the transmitter of the "Paris."

The Radio Industry

It is evident that the radio industry has expanded to undreamed of proportions within the past few months. It is not surprising, therefore, to learn that one concern expects to do a business of well over $50,000,000 this year, judging by the returns of the past few months. There is an ever-increasing demand for vacuum tubes; it is estimated that by this writing 75,000 tubes are being turned out a month, and that by the time this reaches the reader the production will probably exceed 100000 tubes per month. Authorities in and out of radio are of the opinion that the radio business as it is now developing is going to be greater than the phonographic industry, which has been doing a business in excess of $400,000,000 per year.

Efficiency of Radio Plants

In a recent issue of *The Electrician* there appears the following editorial comment, which offers sound food for thought: "Apart from the press stunts, of which wireless has been the victim (or conspirator), the thing that most strikes the observer of progress in this branch of electrical service is the enormous dispoportion between the hundreds of kilowatts utilized at the transmitting end and the few microwatts picked up at the receiver. No doubt this apparently inevitable state of affairs has had its influence upon those who have been engaged in the practical development of wireless, for it is only within recent years that any progress has been made in the rounding up and extermination of the losses which take place within the transmitting plant itself. The old spark transmitter had an efficiency in the neighborhood of 15 per cent, but it is only necessary to inspect the oil-cooling system of the high-frequency alternator, the water jacketing of the arc, or the red-hot anodes of the very latest transmitter, the 3-electrode valve, to realize that even present-day apparatus has far to go before it approaches the efficiencies now commonplace in low-frequency and direct-current work.

World-Wide Radio

Every leading nation is interested in establishing a system of world-wide radio. Germany had such a plan before the war, which had a distinctly military tendency rather than a purely commercial attempt to keep in touch with all countries, both far and near. Great Britain has had a world-wide radio plan for many years, and of late the subject has been very much in the forefront of British circles. It is understood that the present plan considers six principal centers between which reliable radio communication is required, namely—Great Britain, Canada, Australia, New Zealand, South Africa, and India. Geographical considerations suggested the postponement of Canada and New Zealand. Of the remaining four, Australia, South Africa, and India form an equilateral triangle about 5000 miles along each side, while England is about 6000 miles from South Africa, 5000 miles from India, and 10,000 miles from Australia. The United States has also a plan for world-wide radio, which is rapidly progressing towards realization.

Radio Link in Telegraphy

Experiments on substitution of a radio transmission link for the customary wire transmission lines on the commercial multiplex printing telegraph, have recently been carried on. Results are given of tests made between New York and Cliffwood, N. J., a distance of 25 miles. The usual outgoing signals from the printer were transmitted by wire to the radio room, where by means of a relay controlling the radio transmitter they were converted into radio signals. The received signals at Cliffwood actuated a polar relay and converted the radio signals back to wire signals which were relayed by wire back to the printed laboratory in New York. These tests showed that 180 words per minute could be satisfactorily sent, according to the *Journal of the Franklin Institute*.

WGY Heard 2,600 Miles

The wireless operator on the steamship Luckenbach has just sent word that on March 30, between the hours of 3:50 and 4:38 in the morning, while the ship was south of Panama in the Pacific at seven degrees north of the equator, he had been able to pick up a musical concert sent out from station WGY in Schenectady. This is by airline a distance of more than 2,600 miles and establishes a new record for the station.

The ship operator, W. W. Braire, reports the time he heard each selection, named each selection, and his letter bears a confirmation of the ship's location signed by the master of the vessel. His report checks up exactly with the log of the concert broadcasted that night.

Prior to the letter from the S. S. Luckenbach, the southermost point reached by the Schenectady station was Tela, Honduras. Richard B. Dudley, chief operator on the steamship Coppename, tied up in the port of Tela, reported that he has distinctly heard the program sent out from WGY on March 16. Other distant southern places which have reported hearing WGY are Santa Clara, Cuba and Mexico City.

Important Dates in Progress of Radio-Telephony

The following are the outstanding events in the development of radio-telephony, as compiled by Professor Philip R. Coursey. One of the most important of all, the invention of the vacuum tube, is omitted from the list, probably because it lies more in the province of sound than of pure radio. The events listed deal directly with the extension of range rather than of audibility.

1885—Experiments with the induction system were carried out by Sir William Preece at Newcastle-on-Tyne. A speaking range of 440 yards was obtained.

1894—Experiments with conduction system successful for distance of one and one-half miles across Loch Ness.

1887—The induction system was utilized in mines. Telephonic communications was established between the surface and subterranean galleries of Broomhill Colliery, 350 feet deep, by A. W. Heaviside.

1899—The conduction wireless telephone was installed between Skerries and Anglesea. Average distance between stations, three miles. A similar installation was also put into use between Rathlin Island and the mainland of Ireland. Range of speech communication, eight miles.

1900—Early experiments by R. A. Fessenden with a special high-speed commutator to obtain a rapid sparking rate. Speech transmitted by ether waves for about a mile, but articulation not very good.

1899-1900—Experiments made with A. F. Collins's electrostatic method were successful up to 200 feet range.

1902—The range of Collins's tests was extended to three miles. Articulation said to be perfect.

1902—E. Ruhmer, in the course of his extensive experiments with the photophone method, succeeded in telephoning over a distance of about four miles on Lake Wan-

Digitized by Google

see, and subsequently at Kiel over a range of about twenty miles.

1906—Successful experiments carried out with a small high-frequency inductor alternator by R. A. Fessenden. Ranges up to about twenty miles obtained.

1906—Tests of art transmitters made by Telefunken Company between Nauen and Berlin—twenty miles.

1907—The range of Fessenden's tests was increased to about 100 miles, using improved H. F. alternators.

1908—Tests with the Colin-Jeance arc apparatus were made from the Eiffel Tower. A range of thirty miles obtained.

1908—Experiments by F. Majorana, using an arc oscillation generator with his liquid microphone, were carried out from Rome to a number of other stations—including ships. The range of successful speech communication was gradually extended from about thirty-five miles to 156 miles (Rome to Sardinia), then to 180 miles (Rome to Maddalena), and eventually to 300 miles (Rome to Sicily).

1908—V. Poulsen succeeded in transmitting speech over a distance of about 150 miles, using his arc transmitter.

1909—Successful tests of Poulsen type arcs between Milwaukee and Chicago (ninety miles).

1909—Ranges of speech communication up to seventy-five miles obtained with Colin-Jeance arc apparatus; subsequently increased to 100 miles between Toulon and a French cruiser, and ninety miles between Eiffel Tower and Dieppe.

1910—Experiments with H. P. Dwyer's arc gave perfect telephonic communication between San Francisco and Los Angeles—490 miles range.

1911—Range of speech communication from Nauen increased to about 350 miles (Nauen to Vienna).

1912—G. Vanni obtained a speech range of 600 miles between Rome and Tripoli, using the Moretti arc oscillation generator and the Vanni liquid microphone.

1913—Experiments at Nauen Station with 10,000-frequency alternator and static frequency raiser gave a range of 550 miles to Pola.

1913—Experiments at Nauen Station with 10,000-frequency alternator and static frequency raiser gave a range of 550 miles to Pola.

1913—Further experiments carried out with the induction system in mines demonstrated its special utility for such purposes. Communication was successfully established between the surface and a level 800 feet deep.

1914—The T. Y. K. arc system was first put into practical use at Toba.

1914—Successful speech communication from Brussels to Paris, 190 miles, using Moretti arc transmitter and Marzi's carbon powder microphone.

1914—Experiments carried out by G. Marconi with the oscillating valve transmitter on Italian war vessels. Ranges up to forty-five miles were obtained, using very limited power at the transmitter.

1915—Tests of oscillation valve transmitters gave successful communication between New York and California, 2,500 miles.

1915—The American Telephone and Telegraph Company carried out a series of very successful experimental tests with the valve type transmitters. Eventually the Atlantic was bridged between Arlington (Va., U. S. A.) and the Eiffel Tower, France, 3,800 miles, and good speech communication was also established between Arlington and Honolulu, a distance of close on 5,000 miles. Articulation was said to be faint, but very clear and recognizable.

1918—Considerable development of wireless telephone apparatus for communication with aircraft. Successful results obtained up to about 100 miles between aeroplanes in flight, and up to about 150 miles between aeroplanes and the ground.

1919—Successful wireless telephone communication established between the British Isles and Canada by special valve apparatus developed by the Marconi Company.

Business Firms Use Radiophone

The farmers in the Middle West for some time past have been receiving their weather and crop reports over the wireless telephone, broadcasted by the Government. Now enters the New York business man who sees a step forward in the adoption of the wireless telephone for general business.

Kaye & Einstein, manufacturing furriers, have installed a wireless telephone receiving station, which is connected with each of their nine selling booths A customer in these booths can pick up a receiver at any time, and listen to market reports, news of the day, crop and weather conditions throughout the country, financial reports, or the machine can be adjusted so that he will receive the music of a concert to soothe his frayed nerves. The machine has an amplifier connection with the factory, so that the working people may receive music and entertainment during working hours. The outfit is a very powerful one and will pick up messages from Pittsburgh, Chicago and points from a greater distance.

Built-in Vernier Best

If the very best is desired in a set that employs variable condensers for tuning, get condensers that have verniers built in. These are two-plate condensers, mounted directly on the main shaft and controlled by a separate arm. Rough adjustments are made on the big condensers, and very fine regulation is made with the verniers. The latter, before being touched, should be kept in half way, so that adjustments can be made either way, as necessary.

Grid Leak Important

Too much emphasis cannot be laid on the importance of the necessity of the right value of the grid leak. If it is not correct the set will howl unmercifully. Do not buy grid condensers with the leaks already built in. Buy a separate grid condenser, and either make or buy a leak that can be varied easily, such as the pencil line type. If the set does howl, try rubbing out some of the lines, and if the set doesn't work the way you think it should, try rubbing some more on.

New Regulations Use Radio to Aid Seaplane Fliers

Seafaring aeroplanes will be as safe as a chair at the opera if all the new regulations announced by Secretary of the Navy Denby are strictly enforced.

The regulations provide that all aeroplanes that make long passages be equipped with radio sets of sufficient strength to communicate with a ship or station at the near end of the passage. Machines will be required to go in pairs in all cases where a forced landing in a locality where any difficulty in finding a place of landing for the machine might be encountered. Even if a 'plane is equipped with a satisfactory radio set, it may fly so near to the ground in inclement weather that it would find it impossible to signal distress between the time that the engine fails, and the moment of landing. As stated in the announcement recently made by Secretary Denby, "When one machine is forced to land suddenly, the other finds out by a visual signal whether its mate needs help or whether repairs can be made in a few minutes.

"If the aeroplane down is able to continue its flight in a few minutes, the machine in the air continues circling overhead, makes a radio report of the circumstances, and when its mate has taken off, reports that the flight is resumed. If the aeroplane down must take a long time to make repairs or require a tow to get to port, the machine in the air reports the circumstances by radio and then goes alone to its destination."

In cases of distress when immediate assistance is needed the second machine flashes a report to this effect, and then lands, where possible, to lend assistance to the disabled 'plane.

In addition to making forced landings the leader of each pair of 'planes will be required to make a report of their position each half hour. If both 'planes are forced down simultaneously, then, with opportunity for flashing a signal, the ship or station will be able to approximate their position with a fair degree of accuracy.

Congressman Proposes Radio Station in Capital

The bill introduced by Congressman Vincent M. Brennan of Michigan, serving his first term in the House of Representatives, to install a powerful radio transmitter on the floor of the House, indicates an entirely new field of radio activity.

Hitherto the radio has been employed on a large scale to broadcast news of public events—reports of political events, athletic and sporting contests, public conditions, etc.—but with the passage of Congressman Brennan's bill and the subsequent opening of the Congressional station, the events themselves would be broadcasted. It would be the difference between seeing a prize fight and reading about it in the newspapers.

Entire new vistas open themselves if this measure is approved. Wireless transmitters at diplomatic parleys, thus actually obtaining "open covenants openly arrived at." Perhaps some day it will be possible to get all the thrills of a murder trial without being crushed by the mob struggling to get in the court room.

Aerial Still Perplexes Many Beginners at Radio

The aerial is a point that has not yet been thoroughly cleared up in the minds of many beginners. The aerial should be composed of one wire about 100 feet long. Remember that two wires each fifty feet long will not give the same results and also that the aerial should run all in one direction. The aerial that is full of bends is not very efficient and a straight line aerial is far superior. The lead-in should always be taken from one end, as the T aerial is not particularly good for receiving. The short end of such an aerial is absolutely wasted, and is not helping the set a single bit. The indoor aerial is not much good unless there are several stages of amplification used, and is far below the outdoor aerial in efficiency. Several people have written in, disputing this claim, but probably their outdoor aerials have not been constructed correctly. The indoor aerial will not work with a crystal set unless the owner is located very near the station that he wants to receive.

The wire in the aerial should be of copper of almost any size as long as it is strong enough to support its own weight. Remember that some of the smaller sizes of wire will not withstand the rigors of a sleet storm, and the owner does not want to keep erecting a new aerial every time it comes down.

What Is Your Problem In Commercial Aviation?

GETTING STARTED? All right, we have a stock of Airplanes and Motors ready to fly.
KEEPING GOING? We can help you hecause we are the largest commercial aviation supply housa in tha country.
SERVICE? Johnson Service means good service, including a modern equipped flying fiald and shop.
INFORMATION? Our information department is at your service free of charge.
PRICES? Lowest prices consistent with hest material.
GUARANTEE? Our customers must he satisfiad always, or their money refunded.

Let us solvo your problems in commercial aviation. Write us first and avoid costly delays. Our new catalog mailsd on request.

A FEW SUGGESTIONS TO MAKE YOUR PLANE LOOK SNAPPY:

New Flottorp propeller, copper tipped $30.00
New radiators, Curtiss or Standard 20.00
New upholstered wicker seats 3.00
New side cowl or cock-pit cowl Curtiss or Standard 15.00
New streamlined wheels, 20x4 ...... 10.00
New Goodyear cord tires, 26x4 ...... 10.00
New fuselage covers, ready to put on, Curtiss or Standard $15.00
New wind shields 2.00
New shock absorbers, per foot ...... .05
New safety belts, American type 3.00
New center section with fittings, for Standard 10.00
New hose connections, all types ...... .10
New hose clamps, all sizes ...... $ .10
New Hartsell propeller, new design, brass tipped 00.00
New Warner tachometer with shaft 8.00
New thermometer, 15 ft. tube 7.00
New altimeters, 20,000 foot, luminous dial 10.00

JOHNSON AIRPLANE AND SUPPLY CO., DAYTON, OHIO
LARGEST COMMERCIAL AVIATION SUPPLY HOUSE IN THE COUNTRY.

WE HAVE SOLVED THE PROBLEM

42 PLANES SOLD FROM JAN. 1st to MAY 1st

THEY MUST BE GOOD AND OUR PRICES MUST BE RIGHT

THE SOLUTION: NEW 3 SEATERS $950.00 to $1500.00

NEW 5 SEATERS $2000.00 TO $2500.00. USED JN's $650.00

All completa and raady to fly away, with free instruction if you need it. Wa are in the gama because wa lika it and prefer to take small profits and keep things moving.

DO NOT DELAY — OUR SUPPLY IS LIMITED

CHAMBERLIN AIRCRAFT — NEW YORK AIR TERMINAL (6 Milas from N. Y. City) — **Hasbrouck Heights, N. J.**

NOW AVAILABLE FOR YOUR AUTO

"The Plug That Cleans Itself"

Saves Gas **B-G** More Power

GUARANTEED CARBON AND OIL PROOF

Recognized as the best for aeroplanes, its success for automobiles is assured

B - G CORPORATION
33 Gold St., New York

If your dealer cannot supply you, send us his name and $1.00 for each plug, stating name and year of manufacture of your car.

WRITE FOR INFORMATION on our flying course. Lowest prices on new and used OX5 motors. Wallace Bros. Aero Co., Bettendorf, Iowa.

WANTED—Grade A Cotton. We will also buy any and all kinds of Canuck, JN4D, or Standard supplies and material. What have you for sale? Let us rebuild or buy your crash. Cantwell Aircraft Co., Bucklin, Mo.

YOUNG MACHINIST, 21, five years' experience, desires to learn aviation from bottom up, with a reliable company anywhere. Good reference. Write Box 671, c/o AERIAL AGE WEEKLY, 5942 Grand Central Terminal, New York City.

STANDARD J1 planes complete, less motor, $625.00. Complete new wing sets, wires, struts, tail unit, never uncrated less than $200.00. Single panels crated $57.50, new landing gears complete $80.00. Wing skids $2.00. Wind shields $2.00. Side cowls $4.00. Dope fifty gallon barrels $50.00. Propellers new copper tipped OX5, OXX6, Thomas Morse Scout complete $450.00. Mercedes motor, 6 cylinder, 160, $375.00. Air speed indicators $20.00. Thermometers $6.50. Write Marvin A. Northrop, c/o Minneapolis Athletic Club, Minneapolis, Minn.

DOPING-VARNISH BRUSHES $2.25; various gauges locking safety wire (copper). Special—only 50c pound (worth double). Highest grade spruce, sheet steel. Everything aeronautical. Ostergaard Aircraft Works, 4271 North Narragansett, Chicago.

MODEL AEROPLANES AND SUPPLIES— Let us supply you. Send for our latest catalog. 10c brings it to you. Wading River Mfg. Co., 672-AB. Broadway, Brooklyn, N. Y.

CURTISS AND AVRO PLANES — Curtiss JN4D, new, without motor, condition perfect, $550.00. Avro complete, LeRhone motor, perfect condition, $1200.00. Can furnish Curtiss motors. Write Box 668, c/o AERIAL AGE WEEKLY, 5942 Grand Central Terminal, New York City.

FOR SALE—J1 Standard in A1 condition. Motor perfect condition, nicely painted. A real bargain $850.00. M. L. Powell, Box 214, Stanberry, Mo.

PERFORMANCE

THE RECORD for both the greatest number of passengers carried and the greatest tonnage of express transported on the Paris-London Line—the busiest air-route in the World—is held by the 14-Passenger Farman "Goliaths."

This is the *Fourth Year* of regular Farman Air Transportation Service.

Farman "Goliath" Airlines carry capacity loads — the cream of the business — wherever there is competition in Aerial Transportation.

Shouldn't such excellent service be available today in the United States?

Learn to Fly

Aviation is making such strides that it needs more men right now

You Can Learn To Fly

I can teach you how to become a successful pilot in a short time. My course is so arranged that you get only the things you need to make you a good aviator.

The Diggins Extension Course

is up-to-date, teaches you what you must know to become an expert flyer. This course is written by competent instructors right on my flying field. It is kept right up to the minute—all new developments in aviation are included. That is why it is recognized as the most complete and practical course offered today. My course saves you time and money because it prepares you at home so that you are ready to begin flying the day you arrive at the flying school.

Superior Points of the Diggins School

1. The Diggins school is the oldest, largest and most complete commercial aviation school in America.
2. The Diggins school is located in Chicago, the center of Aviation.
3. Living quarters and free employment service are maintained for students.
4. Diggins guarantees to make you a pilot.
5. Diggins' pilots get top notch salaries.
6. References, any aero club in America.

WRITE TODAY Write today for the new Diggins beautifully illustrated catalog.

We have purchased from the Navy all the remaining MF Flying Boats, 57 in number.

These are new, unflown and in perfect condition.

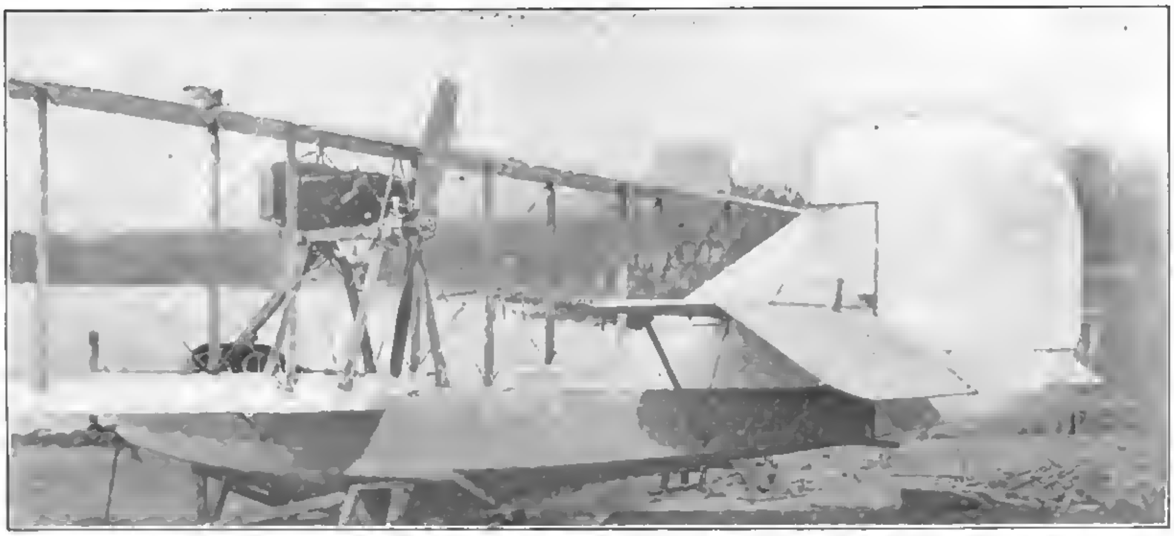
Our prices are:

MF Flying Boat, without engine, f. o. b. Philadelphia or f. o. b. Pensacola, Fla. .... **$ 675.00**

MF Flying Boat, two seater, with 100 H.P. OXX 6 motor installed, ship completely tuned up and ready for flight, f. o. b. College Point, L. I., N. Y. **$1,700.00**

MF Flying Boat, reconverted to 3 seater, equipped with 150 or 180 H.P. Hispano, f. o. b. College Point, L. I., N. Y. Model CK-14....... **$2,900.00**

Flying instruction on purchaser's boat will be given at a nominal figure.



The MF with 180 Hispano, our model CK-14, is a splendid Flying Boat with a maximum speed of 88 miles per hour and a ceiling of 9,500 feet.

This is **a real opportunity,** probably the last of its kind.

Profits!

Pilots make real money from flying JN'S. Some have made enough in one week to pay for their machines, many are making from $100 to $300 a day carrying passengers. Tens of thousands of people enjoyed their aeroplane rides last year and many more, perhaps hundreds of thousands, will enjoy their flights this year. They will ride and be convinced of the comfort, ease and pleasure of air travel. And the great majority will fly in Curtiss Aeroplanes because everyone knows that Curtiss Aeroplanes combine

RELIABILITY
STRENGTH
PERFORMANCE
ECONOMY
COMFORT

They are the standard of the world. Pilots know that the Curtiss reputation is their protection and consequently the best and most successful flying organizations in America are today using Curtiss Passenger-Carrying Aeroplanes and Motors. Flying schools, aerial photography, aerial advertising, Curtiss Sales and Service are only a few of the many profitable business opportunities open for live business men and pilots.

USED JN'S FROM $650 UP
READY TO FLY

Watch this space for list of America's best flying organizations — of course they use Curtiss Aeroplanes.

Navy to Use Metal Seaplanes

SECRETARY DENBY of the Navy Department on May 7 authorized an announcement that the Glenn L. Martin Company of Cleveland, Ohio, has undertaken the development for the Naval Bureau of Aeronautics of a number of seaplanes to be constructed of duralumin, a special alloy of metal, and to be used by the fleet for spotting gunfire at long ranges.

The construction of metal aircraft of duralumin is a departure for this firm, which hitherto has built planes of the ordinary wood and wire type, such as the well-known Martin bombers which were used last Summer in the aeroplane bombing attacks that destroyed a number of former German ships off the entrance to the Virginia Capes.

The development of metal aircraft construction in the United States, Secretary Denby said, has been made possible by the Navy Department in that the special alloy metal, duralumin, originally developed in Germany, has been introduced to American manufacturers in connection with the construction of the rigid airship ZR-1 at the naval aircraft factory at Philadelphia. This work has now progressed to the point, according to naval aviation experts, where duralumin of proper quantity, and in all of the useful shapes is now available to any aircraft builder from at least two American commercial sources. The naval aircraft factory at Philadelphia has also developed special machinery and processes for its fabrication.

Aircraft manufacturers transacting business with the Bureau of Aeronautics of the Navy have been invited frequently to visit the factory at Philadelphia to observe the metal fabrication of the work that is going on there. Besides the construction of the giant rigid airship ZR-1, the parts of which are being manufactured at Philadelphia for erection at the naval air station at Lakehurst, the factory is also building metal wings, pontoons and other parts for seaplanes.

Just as the surface fleet of the navy passed by the stages of evolution through the era of wood into that of steel, so it is predicted by experts that the air fleet of the naval service will proceed from the period of wood and linen to that of metal.

Secretary Denby said that the Stout Engineering Laboratories, Inc., of Detroit, were also working with duralumin. This firm has received a contract from the Navy Department for the construction of experimental torpedo-carrying seaplanes to be built entirely of metal, and a simple machine of this character is now under trial flights. Other manufacturers in work for the Navy, it was disclosed, have employed duralumin for parts of aeroplanes with success, notably the Gallaudet Aircraft Corporation of Providence, R. I., and the Aeromarine Plane and Motor Company of Keyport, N. J.

"It is expected," said Secretary Denby, "that future naval aircraft will be built of metal, to an increasing extent. The advantages of metal over wood are especially important for tropical service."

New Recording Devices

AFTER nearly twenty years of flying without knowing just how it was done, new instruments have been devised by the aeronautical experts and pilots of the National Advisory Committee for Aeronautics by which can be recorded what an aeroplane pilot does and how the aeroplane responds. Three special instruments have been perfected to record the speed of the aeroplane in the air, the loadings or changings in weight on the wings and the movement of the controls by the pilot.

Although these instruments are fairly complicated, their operation is simple and mechanical. The recording is done by means of a photographic film. The results reveal for the first time a practical method of securing information in testing new types of aeroplanes and of determining the ability and technique of a pilot. The last function of the instruments will be of great value to the pilots themselves and to instructors of novices, who are seldom able to recall just what they did with the controls at a certain point of a flight.

The first of these new instruments is an air speed meter. Another is used for recording variations in the loading on the wings in flight and the landing carriage when landing, taking off, or running along the ground. In flying through a loop, for example, the pilot is sitting down hard as he goes up and again as he flattens out, but he is literally hanging in his belt at the top of the loop. It is these variations in load on the wings due to the weight of the aeroplane and the aviators in the air, that are recorded by this instrument and also the weight on the carriage while on the ground.

The third device—a control-position recorder—indicates the exact position of all the controls during any manoeuvre or part of a flight. When the pilot gives his ship left-rudder it is recorded in degrees. When he dives by pushing on his "stick," or pulls it back to lift the nose, the movements are shown on the record of the flight. After he lands, there is no argument to what he did, for it is plotted from an automatic record. If one pilot reported that a certain aeroplane was not controllable, he could be checked up by having another pilot put the aeroplane through the same manoeuvres, and then comparing the records of both pilots as delineated by the new instrument.

"These three instruments," the National Advisory Committee for Aeronautics said in a statement issued to-night through the Navy Department announcing their development, "are synchronized to operate simultaneously by means of a timing device which makes possible the co-ordination of the three records into a composite one for study and analysis. The instruments themselves are not bulky, and they do not interfere with the movements of the pilot or the operation of the aeroplane. All the attention they require is the throwing of a switch before a manoeuvre is begun and when it is completed to set them all in operation and to stop them.

"When the flight is completed the photographic records with their delineations of the pilot's movements and the aeroplane's

(Concluded on page 232)

THE NEWS OF THE WEEK

British Airship R-36 Declined by America

The United States Government has declined an offer by the British Government to turn over the rigid airship R-36 in final settlement of the account over the destruction of the ZR-2.

It is understood the reason for the American refusal to take the airship was based on the fact that to change her back from commercial to military service would mean a large expenditure of money, which Congress might be unwilling to provide.

Further, it has been decided, for the present at least, to keep clear of foreign built airships, this being determined upon in consequence of the loss of the ZR-2 and the Roma.

The American Government, however, has not abandoned airships, and is going ahead with the construction of the ZR-1, at Philadelphia and Lakehurst, N. J. It will be a year, however, before the airship is finished.

British World Flight

LONDON.—Major W. T. Blake of the Royal Air Force has been invited to take the place of Sir Ross Smith in the proposed round-the-world flight, The London Evening Star announced April 27.

Major Blake told the Star he was taking Captain Norman MacMillan, but he had not decided on the type of flying machine to be used. The route will be through France, Italy, Greece, Egypt, Mesopotamia, India, Eastern China, Japan, thence via the Aleutian Islands across to Alaska, through the United States to New York, thence to Newfoundland and then across the Atlantic via Greenland and Iceland to Scotland.

Major Blake expects to start about the end of May and plans to complete the trip in two months.

Protests Against Reduction Appropriation Army Air Service

Protests were made by Major Gen. Mason M. Patrick, Chief of the Air Service, and Brig. Gen. William Mitchell, Assistant Chief of the Air Service, in a hearing that was accorded them by the sub-committee of the Senate Committee on Appropriations on April 12. They were accompanied by Lient. Col. A. L. Fuller and Major J. Y. Chisum, of the Air Service, and Dr. R. B. Moore, Chief Chemist of the Bureau of Standards.

General Patrick discussed at length the reduction that would restrict the activities of the Service with the Organized Reserves and the R. O. T. C. General Mitchell discussed lighter-than-airships, and the importance of maintaining the enlisted personnel of the Air Service.

General Patrick objected very seriously to the cut of $260,000 made by the House in the appropriations for civilian personnel. He showed how this would interfere with the operations of the Service. The general explained that the House had made a reduction of $810,000 in the allowance for normal operations; a reduction of $201,000 in the appropriations for field hangars. He also called attention to the importance of appropriating sufficient funds for experimental research, so as to keep the Service abreast with the progress of aviation.

General Mitchell, who recently returned from Europe, strongly argued for adequate appropriations for lighter-than-airships. He pointed out the value of lighter-than-airships, giving an account of how aeroplanes were launched from dirigibles. He also described how experiments in foreign countries were being made by landing aircraft on suspended wire-arrestors. These wire-arrestors, he explained, would greatly increase the value of lighter-than-airships.

General Mitchell in discussing the personnel problems declared that it was necessary to keep up the enlisted personnel of the Air Service in order to maintain the equipment of the Air Service.

Both urged legislation for a distinguished flying cross to be awarded for extraordinary hazardous and important missions in the Air Service. They cited an instance of the Atlantic Ocean flight as a need for such a decoration.

Dr. Moore explained the necessity for an increase of the appropriations for helium gas, if the gas was to be manufactured in sufficient quantities for the Army and Navy.

Kentucky Encourages Aviation

That the State of Kentucky is fully cognizant of the important rôle slated for aviation in the economic and industrial life of the country is manifested by the recent action of the State Legislature in passing a Resolution requesting all towns and cities in the Blue Grass State to print in large letters the names of such respective towns and cities in such conspicuous place as may be observed by aviators passing over such towns and cities.

Captain Harry B. Flounders, Air Service, stationed at Camp Knox, Ky., is directly responsible for the introduction and passage of this Resolution. This officer is also endeavoring to work up interest in aviation in the other states of the Fifth Corps Area, in order to have a similar Resolution passed. Officers stationed at Godman Field, Camp Knox, Ky., are giving lectures at various localities throughout Kentucky, and the State is taking a very active interest in the development of aviation.

It is hoped that the worthy example set by the State of Kentucky will soon be followed by the other states of the Union, as the importance of such identification signs cannot be overestimated. Several aviation accidents have occurred by virtue of the fact that aviators have lost their bearings and, being forced to fly low in order to catch some identification sign of the town, they were flying over, collided with some telegraph wires or a building or found it necessary to land in a restricted place.

The Resolution, as passed by the Commonwealth of Kentucky, is as follows:

"Whereas much interest is being taken in the subject of aviation, especially in the subject of carrying the mails by such method, and,

Whereas aviators experience much difficulty in ascertaining the name of many towns and cities over which they are flying; and,

Whereas there are but few natural objects near the many towns and cities in this Commonwealth whereby such aviators passing over the same can ascertain the names of such towns and cities; therefore,

Be it Resolved by the General Assembly of the Commonwealth of Kentucky:

Section 1. That the Mayors of all towns and cities in this Commonwealth are hereby requested to have painted in letters sufficiently large to be seen at a considerable distance, the name of their respective towns and cities upon the top of some building or eminence in order that aviators in passing over such towns and cities may be able to ascertain readily the name of such town or city.

Section 2. That the Clerks of the Senate and the House of Representatives of the General Assembly of Kentucky shall transmit certified copies of this resolution addressed to the Mayor of each town and city in this Commonwealth."

Spokane News

Spokane, Wash.—With the status of the Parkwater municipal aviation field settled, as under the direct control of the city parks board with regulations to be governed by federal rules, C. H. Messer, head of the United States Aircraft Corporation, has announced plans for extensions, including immediate reduction in rates.

A new three-passenger and pilot plane has been put into service, in which a party of three can make a trip anywhere. It will be operated by Nick Mamer, chief pilot for the concern.

Work has begun installing radio equipment at the hangar and on the ships. Workmen also began the construction of markers on both the lower field, now in use, and the upper or east-end field, at the northeast corner of the city's tract.

At its last meeting the park board decided to make no lease for the field and to operate it as a municipal field, open to the public, with any flyer being privileged to use the field by the securing of a permit and the payment of $5 per ship per season. Desire to foster aviation, rather than to get money out of the field, prompted the board in its action.

Mr. Messer, who now uses the field and has a hangar for four ships constructed there, was given the first permit.

Tom Symons and Bill Barnard, local flyers, announced that they would make Mr. Messer's hangar their headquarters here.

An agency for Curtiss ships and products has been secured by Mr. Messer.

Aero Club of Jordan, Mont.

An aero club has recently been organized at Jordan, Mont., as an auxiliary of the Aero Club of Miles City. The members and officers are: Mr. Floyd Tollefson, President; Mr. S. C. West, Vice-President; Mr. G. B. Hart, Secretary-Treasurer; Mr. H. A. Hetherington and Mr. George Ayer. These are all prominent business men in their town which is located 40 miles from the nearest railway.

Medina Aviation Club

The Medina Aviation Club has been organized at Medina, Ohio. H. R. Calvert is president and general manager, A. B. Pritchard, secretary and treasurer, W. P. Goembel, instructor, and J. A. Ray, chief mechanic. The club has taken over the Budd Sanford outfit of Brunswick, Ohio, and is operating a "Canuck" and a "Waco" Model 4, built by the Weaver Aircraft Co.

The AIRCRAFT TRADE REVIEW

Cox-Klemin Purchase M.F. Boats

The Cox-Klemin Aircraft Corporation, of College Point, Long Island, have purchased 57 MF. flying boats from the Navy Department. The boats are in excellent condition, the majority of them never have been uncrated. Some of the boats will have 0xx6 motors installed, and those who desire a more speedy boat will have 180 h.p. Hispano motors.

Business Men Willing To Pay Air Mail Rates

Washington.—Business men generally would be willing to pay extra postage on air mail provided the safety of the mail and quick and certain delivery could be guaranteed, representatives of the Aeronautical Chamber of Commerce, the Merchants Association of New York and other organizations contended April 28th before the House Postoffice Committee. The Steenerson bill, under which the Postmaster general would be authorized to provide star air routes, was up for hearing.

F. B. De Berard, of the merchant's association, said if a highly improved method for expediting the mail were adopted, the public would rapidly avail itself of its use. But to be effective the aeroplane service must be operated by night, with plenty of equipment and landing, repair and supply stations, he added.

The Steenerson bill would fix the first class rate of postage on air mail at not less than 6 cents for each ounce or fraction, and would authorize the Postmaster General to contract with companies for transportation of first class mail by aircraft at a rate not exceeding two mills a pound a mile, and mail other than first class at a rate not exceeding one-half a mill a pound a mile.

Weaver Aircraft Company Moves

The Weaver Aircraft Company, manufacturers of the "Waco" Model 4 and the "Cootie" one-passenger baby plane have moved to Medina, Ohio, thirty-five miles southeast of Lorain, and are now manufacturing several planes on contract. They are receiving a large number of inquiries from all parts of the country regarding the "Waco" Model 4.

Air Mail Division Sale

Sealed proposals will be received at the office of the Second Assistant Postmaster General, Washington, D. C., covering certain aeronautic equipments, full details of which can be secured from C. F. Egge, General Superintendent, Air Mail Service.

The Santa Maria

The Aeronautical Chamber of Commerce of America, 501 Fifth Avenue, New York City, on April 26 pointed to the safe arrival at Nassau of the flying cruiser "Santa Maria" (mentioned in newspaper dispatches from Miami, Florida as having been out overnight in the Gulf Stream) as another indication of the safety of over-water, aerial transportation when conducted by a Company sufficiently well organized and financed to maintain their equipment in the best possible condition.

The "Santa Maria" which is operated by the Aeromarine Airways left Key West for Nassau Monday on a three hundred and fifty mile emergency flight.

Due to the fact that they were compelled to buck a strong head wind which greatly retarded their speed, the pilot on seeing that his gas supply was getting low decided to come down at Billy Island in the Bahamas and after sighting a small harbor made a safe landing, taxied up to the beach and awaited gasoline which he knew would be sent out by the relief boat.

In the meantime, the passengers amused themselves strolling up and down the beach and preparing a good dinner from the supply of rations aboard the ship.

As soon as possible the passengers were transferred to a fishing schooner and taken on to Nassau. When the Navy flying boat under the command of Captain Bartlett and Lieutenant Miller located the "Santa Maria" they sent out a wireless stating where she was located, then made a landing and supplied the "Santa Maria" with sufficient gasoline and she continued on her course to Nassau.

The Aeromarine Airways, which operates a fleet of flying boats between Florida and points in the Bahamas and the West Indies, have flown over 150,000 miles, carried over 10,000 passengers without a single serious mishap.

In commenting on the experience of the "Santa Maria," C. F. Redden, President of the Company said: "We did not have the least apprehension for the safety or even the comfort of the passengers on the "Santa Maria" because the boat is as much in its element on the sea as it is in the air. It was equipped with two 400 horsepower Liberty motors and even tho they were compelled to land at sea on account of motor trouble, the auxiliary motor would enahle her to taxi to some safe harbor.

"The boat is a huge eleven-passenger enclosed-cabin cruiser provided with sufficient food and water to maintain its passengers for a week and the big reclining chairs and settees which are more comfortable than the average Pullman reclining chairs were such that the passengers need suffer no hardship either night or day.

"Our system of rigid inspection and maintenance has enabled us to operate successfully for two years without serious trouble and the wonderful record of these flying boats in the service of the United States Navy is an eloquent testimonial to their sea and air worthiness and general reliability."

The "Santa Maria" will leave Nassau in a few days for Washington and New York where it will be in regular service between New York and Atlantic City.

Assistant Aeronautical Engineer

The United States Civil Service Commission announces an open competitive examination for assistant aeronautical engineer. A vacancy in the position of aeronautical engineer, Naval Aircraft Factory, Navy Yard, Philadelphia, Pa., at $7.20 per diem, and vacancies in positions requiring similar qualifications, at this or higher or lower salaries, will be filled from this examination, unless it is found in the interest of the service to fill any vacancy by reinstatement, transfer, or promotion.

Applicants should apply for form 1312, stating the title of the examination desired, to the Civil Service Commission, Washington, D. C.

The Airplane Engine

The author, Lionel S. Marks, Professor of Mechanical Engineering, Harvard University, presents in this book a treatment of the aeroplane engine that is so thorough and detailed that it will be accepted at once as the standard work in this field.

It is the first adequate discussion of the aeroplane engine, design and construction to be published in this country.

It is based mainly on the researches and engine developments originating during the war and resulting from the war's urgencies. It includes the results of investigations carried on by the United States, the British, the French and the German governments.

The chapter headings are: Power Required and Power Available, Engine Efficiencies and Capacities, Engine Dynamics, Engine Dimensions, Materials, Engine Details, Valves and Valve Gears, Radial and Rotary Engines, Fuels and Explosive Mixtures, The Carburetor, Fuel Systems, Ignition, Lubrication, The Cooling System, Geared Propeller Drives, Supercharging, Manifolds and Mufflers, Starting, Potential Development.

Pistons

The Aluminum Manufacturers, Inc., Cleveland, have just published "Pistons—A Reference Book," which should be in the hands of every engine mechanic. It discusses the functions of pistons, piston troubles, piston design, and things to be observed to insure successful piston operation.

LANDING FIELDS IN THE UNITED STATES

The following landing fields have been reported to the Office of the Chief of Air Service, War Department, since January 1, 1922:

Arkansas

Ogden.—Latitude 33° 35′ N., longitude 94° 00′ W.
Reported by the National Aircraft Underwriters Association; no data.
Van Buren.—Latitude 35° 24′ N., longitude 94° 21′ W. No data.

California

Colfax.—Latitude 39° 07′ N., longitude 120° 57′ W.
Small emergency field, 600 by 300 feet; soft, wet, level; ½ mile south of city; altitude 2,422 feet.
Courtland.—Latitude 38° 20′ N., langitude 121° 30′ W.
Emergency; 129 miles from Reno, 58 miles from San Francisco; nearest railroad station, Hood; long distance telephone only; gas and oil; ½ mile east and 3 miles southeast of town are large level cultivated fields where safe landing could probably be made, but take-off difficult owing to soft ground or growing crops. Landmark, Grand Island Drawbridge, 2¼ miles south of town.
Elsinore.—Latitude 33° 40′ N., longitude 117° 20′ W.
Emergency, good; located south of town and railroad, one mile west of river and north of lake; square; 40 acres; garage service; altitude 1,300 feet.
Franklin.—Latitude 38° 25′ N., longitude 121° 25′ W.
Emergency; 122 miles from Reno, 65 miles from San Francisco; Western Pacific Railroad; long distance telephone and telegraph; gas and oil; tract for landing field adjoining town and ¼ mile southwest of railroad. Landmarks, church in one corner of field, Western Pacific Depot, and Great Western Power Company's towers.
Freeport.—Latitude 38° 27′ N., longitude 121° 30′ W.
Field 1,800 by 2,000 feet, located 115 miles from Reno and 72 miles from San Francisco, on Southern Pacific Railroad. Long distance telephone only; gas and oil. Landmarks, two steel towers, 185 feet high, one on each side of the Sacramento River, west of town.
Garden Valley.—Latitude 38° 52′ N., longitude 120° 50′ W.
Field 72 miles from Reno, 115 miles from San Francisco; nearest railroad at Placerville. Southern Pacific, about 12 miles by road. Long distance telephone only; no supplies; not a good landing place; very rocky and hilly.
Georgetown.—Latitude 38° 55′ N., longitude 120° 50′ W.
Field 70 miles from Reno, 117 miles from San Francisco; 18½ miles to Placerville, nearest railroad staion; long distance telephone only. Field unplowed land 1,800 by 3,000 feet, located 1 mile east of town; slight grade, no obstructions; a large isolated hill on eastern boundary.
Holtville.—Latitude 32° 45′ N., longitude 115° 24′ W.
Emergency; southeast and near town; 2,500 by 2,500 feet; another field further southeast.
Mills.—Latitude 38° 36′ N., longitude 121° 20′ W.
Mather Field, 103 miles from Reno, 84 miles from San Francisco, on Southern Pacific Railroad; long-distance telephone and telegraph. Field 1 mile south, American River 1 mile north of town.
Natoma.—Latitude 38° 40′ N., longitude 121° 12′ W.
95 miles from Reno, 92 miles from San Francisco; long-distance telephone only; supplies; field covered with dredge tailings. Land at Folsom, 1½ miles north. Natoma painted on both sides of barn.
Perris.—Latitude 33° 48′ N., longitude 117° 15′ W.
High School Field, ¼ mile north, near school and between railroad and boulevard; 30 acres; good in wet weather; supplies; another field 1 mile southeast.
Polaris.—Latitude 39° 23′ N., longitude 120° 10′ W.
Emergency; 22 miles from Reno, 165 miles from San Francisco, on Southern Pacific Railroad. Long-distance telephone only; no supplies; possible landing 1 mile north.
Seeley.—Latitude 32° 50′ N., longitude 115° 42′ W.
Municipal Field (for air mail) west of town; railroad and highway run east and west; supplies.
Shingle Springs.—Latitude 38° 40′ N., longitude 120° 54′ W.
7 miles south and east of the air-mail course, on the Placerville branch of the Southern Pacific Railroad. Field 1,500 by 300 yards, ½ mile west of town, bounded by the highway on the south and the railroad on the north; level, hard, and smooth; altitude 1,000 feet.
Slatington.—Latitude 38° 50′ N., longitude 120° 48′ W.
73 miles from Reno, 114 miles from San Francisco, 6 miles to railroad station at Placerville; telephone and telegraph; supplies; many suitable landing places.
Suisun.—Latitude 38° 15′ N., longitude 122° 03′ W.
Field 2,000 by 5,000 feet; in a strategic position for flying in the Sacramento valley; level, bounded by fences and road on the south; supplies; altitude 100 feet.
Truckee.—Latitude 39° 20′ N., longitude 120° 13′ W.
Good summertime landing, 600 by 2,000 feet, near the junction of Lake Tahoe and Southern Pacific Railroads; deep snows in winter. Maintain altitude of 15,000 feet in crossing the Sierras at this point. Landing field prepared by the citizens 3 miles out on the highway; supplies.
Tracy.—Latitude 37° 43′ N., longitude 121° 27′ W.
Emergency; ball ground, 1,600 by 1,100 feet, between railroad branch and six big tanks and water tower.
Wilmington.—Latitude 33° 44′ N., longitude 118° 17′ W.
Smith Aircraft Company's field, 1¼ miles west of town, 2,000 by 1,000 feet along the boulevard; good in any weather.
Winchester.—Latitude 33° 42′ N., longitude 117° 06′ W.
In Domenegoni Valley; no data.
Yosemite.—Latitude 37° 45′ N., longitude 119° 37′ W.
National Park Field.

Colorado

De Beque.—Latitude 39° 20′ N., longitude 108° 13′ W.
Emergency field in vicinity.
Gypsum.—Latitude 39° 42′ N., longitude 106° 55′ W.
Emergency field in vicinity.
Malta.—Latitude 39° 16′ N., longitude 106° 20′ W.
Level fields for emergency landings; altitude 9,580 feet.
New Castle.—Latitude 39° 34′ N., longitude 107° 32′ W.
Level fields for emergency landings.
Riverside.—Latitude 38° 57′ N., longitude 106° 12′ W.
Level fields for emergency landings.
Wolcott.—Latitude 39° 41′ N., longitude 106° 41′ W.
Level fields for emergency landings.

Connecticut

Stamford.—Latitude 41° 03′ N., longitude 73° 32′ W.
Halloween Park, emergency, 2½ miles south of town.

Florida

Apalachicola.—Latitude 29° 44′ N., longitude 84° 58′ W.
Landing for seaplanes only.
Green Cove Springs.—Latitude 29° 29′ N., longitude 81° 41′ W.
Landing for seaplanes only.
Palatka.—Latitude 29° 19′ N., longitude 81° 38′ W.
Landing for seaplanes only.

Georgia

Thomasville.—Latitude 30° 53′ N., longitude 83° 58′ W.
Spence Field, municipal, 1,100 by 350 feet; good in wet weather; marked by a T within a circle; between highway and railroad; altitude 275 feet.
West Rome.—Latitude 34° 07′ N., longitude 85° 06′ W.
Reported by the National Aircraft Underwriters' Association; no data.

Idaho

Hope.—Latitude 48° 15′ N., longitude 116° 20′ W.
Field situated halfway to Sand Point, north of lake.
Lewiston.—Latitude 46° 25′ N., longitude 117° 03′ W.
Emergency; good; 2,100 by 3,000 feet; northwest of race track; marked by T; altitude 750 feet.

Illinois

Ashburn (Chicago).—Latitude 41° 45′ N., longitude 87° 40′ W.
Aero Club of Illinois Field; 10 miles from Congress Hotel; one mile square; three hangars; soggy when wet; supplies and service by Ralph C. Diggins Company Flying School. (See Notice to Aviators 3 (24) of 1922).
Beardstown.—Latitude 40° 01′ N., longitude 90° 25′ W.
For seaplanes only; difficult landing in cross winds; flying boat anchor must be used; fuel ordered in advance.
Cairo.—Latitude 37° 00′ N., longitude 89° 11′ W.
For seaplanes only; flying boat anchor must be used; fuel ordered in advance; Chamber of Commerce will cooperate.

Indiana

Anderson.—Latitude 40° 05′ N., longitude 85° 40′ W.
32 acres rented and operated by Mr. E. B. Bridges.

Iowa

Missouri Valley.—Latitude 41° 32′ N., longitude 95° 55′ W.
Field of Missouri Valley Aero Co.; hangars, etc., Messer Pasture.
Webster City.—Latitude 42° 28′ N., longitude 93° 48′ W.
Field of the Webster City Aero Com-

Digitized by Google

pany; on northwest edge of town; 50 acres; ideal; canvas hangars; marker; high test gas and oil.

Kansas

Junction City.—Latitude 39° 02' N., longitude 96° 48' W.

Camp Funston; reported by the National Aircraft Underwriters Association; no data.

Lawrence.—Latitude 38° 58' N., longitude 95° 12' W.

Reported by the National Aircraft Underwriters Association; no data.

Kentucky

Barbourville.—Latitude 36° 51' N., longitude 83° 53' W.

Commercial field and flying school.

Lexington.—Latitude 38° 03' N., longitude 48° 30' W.

Race track field.

Louisiana

Houma.—Latitude 29° 35' N., longitude 90° 42' W.

Municipal field; on fair grounds and 16 acres adjoining.

Pineville.—Latitude 31° 20' N., longitude 92° 25' W.

Reported by the National Aircraft Underwriters Association; no data.

Welsh.—Latitude 30° 14' N., longitude 92° 47' W.

Emergency; rice farm, 500 by 1,500 feet; 1½ miles west of town between railroad and highway, near stream; 18 miles east of Lake Charles.

Maine

Auburn.—Latitude 44° 06' N., longitude 70° 15' W.

Northeast Aeroplane Co. Field; small.

Maryland

Cambridge.—Latitude 38° 35' N., longitude 76° 04' W.

Seaplanes only.

Chestertown.—Latitude 39° 12' N., longitude 76° 04' W.

Seaplanes only.

Crisfield.—Latitude 37° 59' N., longitude 75° 52' W.

Seaplanes only.

Easton.—Latitude 38° 46' N., longitude 76° 05' W.

Seaplanes only.

Ocean City.—Latitude 38° 20' N., longitude 75° 05' W.

Seaplanes only.

Oxford.—Latitude 38° 41' N., longitude 76° 11' W.

Seaplanes only.

Salisbury.—Latitude 38° 22' N., longitude 75° 36' W.

Seaplanes only.

Massachusetts

Auburn.—Latitude 42° 12' N., longitude 71° 49' W.

Emergency; 900 by 1,000 feet; stone wall south and east.

Cliftondale.—Latitude 42° 27' N., longitude 71° 01' W.

6 miles north of Boston, on race track. Land east and west on north track only.

Danvers.—Latitude 42° 34' N., longitude 70° 56' W.

Emergency; 30 acres, square; north of reservoir, along road.

Dorchester.—Latitude 42° 18' N., longitude 71° 03' W.

Franklin Field Playground; dangerous; 50 acres; near Boston; emergency only.

Greenfield.—Latitude 42° 37' N., longitude 72° 35' W.

The Meadows Field; ½ mile square; 3½ miles out along road; 2 miles from Deerfield.

Hingham.—Latitude 42° 14' N., longitude 70° 53' W.

Emergency field, 15 miles south of Boston; 1,800 by 700 feet.

Nantasket Beach.—Latitude 42° 17' N., longitude 70° 52' W.

Kenberma Park Field; L shaped, near beach; marked with circle; service and supplies by American Aerial Corporation of Boston.

North Beverly.—Latitude 42° 33' N., longitude 70° 53' W.

Emergency; 25 acres, southeast of reservoir; 3 miles out.

Revere.—Latitude 42° 24' N., longitude 71° 00' W.

Field of the Lynnway Aircraft Corporation; 30 acres; hangars and supplies; along the boulevard between Revere Beach and Lynn.

South Sudbury.—Latitude 42° 22' N., longitude 71° 27' W.

Field of American Aerial Corporation; 15 miles west of Boston; 25 acres, along highway at railroad crossing; marked by the letter A inside a circle; service and supplies.

Michigan

Alpena.—Latitude 45° 05' N., longitude 83° 27' W.

For seaplanes only; moorings not so good on account of town being on open lake; flying-boat anchor must be used; fuel ordered in advance.

Harbor Springs.—Latitude 45° 25' N., longitude 85° 00' W.

No data.

Holland.—Latitude 42° 48' N., longitude 86° 05' W.

Seaplanes only; good landing on lake; flying-boat anchor must be used.

Mackinaw.—Latitude 45° 45' N., longitude 84° 45' W.

Seaplanes only; mooring hazardous except in smooth weather.

Manistique.—Latitude 45° 58' N., longitude 86° 15' W.

Reported by the National Aircraft Underwriters Association; no data.

Manistee.—Latitude 44° 14' N., longitude 86° 22' W.

Seaplanes only; good in open lake if water is smooth; must be taxied between two breakwaters into small harbor; flying-boat anchor must be used.

Muskegon.—Latitude 43° 13' N., longitude 86° 15' W.

Seaplanes only; shallow water and rocks; mooring facilities good.

Petoskey.—Latitude 45° 22' N., longitude 84° 58' W.

Seaplanes only; flying boat can be tied to dock; anchor must be used.

Port Huron.—Latitude 42° 58' N., longitude 82° 24' W.

Seaplanes only; mooring facilities not good on account of current.

Saginaw.—Latitnde 43° 28' N., longitude 83° 58' W.

Fair grounds; ½-mile track; 2 miles east of town; clear approach.

Traverse City.—Latitude 44° 45' N., longitude 85° 38' W.

Seaplanes only; city on open lake; weather must be watched.

Minnesota

Amboy.—Latitude 43° 53' N., longitude 94° 09' W.

Emergency; no data.

Hibbing.—Latitude 47° 28' N., longitude 92° 54' W.

Pritchard Field to south; ideal; to be used by forest patrol pilots.

White Bear Lake.—Latitude 45° 06' N., longitude 93° 00' W.

Harold Peterson Aircraft Co. Field.

Mississippi

Aberdeen.—Latitude 33° 47' N., longitude 88° 27' W.

Fair Grounds; in race track; emergency.

Laurel.—Latitude 31° 42' N., longitude 89° 02' W.

Municipal fair grounds; 830 by 310 feet, in ½-mile track; Madison Station.

Natches.—Latitude 31° 34' N., longitude 91° 20' W.

Seaplanes only; landing facilities good; fuel ordered in advance.

Missouri

Bogard.—Latitude 39° 28' N., longitude 93° 30' W.

Emergency; no data.

Bridgeton.—Latitude 38° 45' N., longitude 90° 24' W.

Emergency; no data.

Clinton.—Latitude 38° 22' N., longitude 93° 46' W.

Owen Farm Field, 1 mile east long road, near cemetery; 40 acres; good when wet.

Ester.—Latitude 37° 51' N., longitude 90° 31' W.

Reported by the National Aircraft Underwriters Association; no data.

Mexico.—Latitude 39° 10' N., longitude 91° 53' W.

Old Fair Grounds Field; 100 acres, two miles southeast of town.

Moberly.—Latitude 39° 26' N., longitude 92° 27' W.

Emergency; no data.

St. Francis.—Latitude 37° 52' N., longitude 90° 32' W.

Emergency; no data.

Willow Springs.—Latitude 36° 59' N., longitude 91° 59' W.

Emergency; no data.

Montana

Bridger.—Latitude 45° 14' N., longitude 108° 57' W.

Curtiss-Montana Aeroplane Company Field, near race track, on runway, 1,800 feet square; soft if wet; hangar barn.

Butte.—Latitude 46° 00' N., longitude 112° 33' W.

Municipal; along stream between Railroad track and road; 80 acres; marked with T; ideal; service and supplies.

Forsyth.—Latitude 46° 14' N., longitude 106° 44' W.

Woolston Field, 2½ miles southeast along road; 600 by 5,000 feet; ideal; hangar and supplies.

Nebraska

Alliance.—Latitude 42° 06' N., longitude 102° 53' W.

Municipal; reddish field ¾ mile west of town; 50 acres; good when wet.

Bushnell.—Latitude 41° 14' N., longitude 103° 53' W.

Emergency field south of town.

Galloway.—Latitude 41° 17' N., longitude 99° 55' W.

Emergency field south of town.

Dunning.—Latitude 41° 50' N., longitude 100° 05' W.

Emergency field; ideal; east of town in fork of river.

Grand Island.—Latitude 40° 55' N., longitude 98° 20' W.

Grand Island Aero Field; 1½ miles east of town; 75 acres marked with T; good when wet; two hangars; altitude 1,700 feet.

Hastings.—Latitude 40° 35' N., longitude 98° 24' W.

College Camp Grounds; 25 acres, 1½ miles south; college buildings east.

Kearney.—Latitude 40° 42' N., longitude 99° 05' W.

Ranch field on Lincoln Highway; across white stone bridge over Platte River; near academy; hangar and supplies.

Digitized by Google

Lexington.—Latitude 40° 46′ N., longitude 99° 44′ W.

Ideal field along road, west of cemetery, 2,640 by 800 feet; good when wet.

Potter.—Latitude 41° 13′ N., longitude 103° 19′ W.

Emergency field about 1 mile west on north side of tracks.

Nevada

Parran.—Latitude 39° 48′ N., longitude 118° 40′ W.

No data.

New Jersey

Brookside.—Latitude 40° 47′ N., longitude 74° 35′ W.

Large unplowed field 58 miles from Mineola, on the railroad. Field of the Eagle Flying Corps; 1,800 feet square, 3 miles from town, east of railroad crossing; red hangar on west; good when wet; mine shaft northeast side; altitude 600 feet.

Elizabeth.—Latitude 40° 40′ N., longitude 74° 14′ W.

Emergency. No data.

Newport.—Latitude 39° 18′ N., longitude 75° 10′ W.

Reported by the National Aircraft Underwriters' Association; no data.

Port Murry.—Latitude 40° 47′ N., longitude 74° 55′ W.

67½ miles from Mineola; suitable for emergency landings; supplies.

Ridgewood.—Latitude 40° 58′ N., longitude 74° 07′ W.

Rouclere Field; commercial; passenger carrying.

Seagirt.—Latitude 40° 07′ N., longitude 74° 02′ W.

Camp Edwards Field; 5,000 by 2,000 feet, along ocean, between barracks and road; very good.

Spring Lake Beach.—Latitude 40° 10′ N., longitude 74° 02′ W.

Emergency; along coast and west of bridge crossing inlet; commercial.

Wrightstown.—Latitude 40° 02′ N., longitude 74° 37′ W.

Camp Dix, 15 miles southeast of Trenton; West Point Cadets in training; emergency.

New Mexico

Garcia Ranch.—Latitude N., longitude W.

Near border monument No. 67; good field with 4-way approach.

New York

Alexandria Bay.—Latitude 44° 20′ N., longitude 75° 55′ W.

Seaplanes only; good landing facilities; use flying boat anchor.

Batavia.—Latitude 43° 00′ N., longitude 78° 11′ W.

Emergency only; fair grounds; poor.

Canton.—Latitude 44° 36′ N., longitude 75° 10′ W.

Fairgrounds; ½ mile track; good field; ½ mile northwest of town.

Cornwall-on-Hudson.—Latitude 41° 26′ N., longitude 74° 00′ W.

Military Academy Field; 500 by 100 yards; good when wet.

Geneseo.—Latitude 42° 48′ N., longitude 77° 50′ W.

Emergency field 1,500 by 1,800 feet, two miles north of town; good when wet.

Lake George.—Latitude 43° 26′ N., longitude 73° 42′ W.

Seaplanes only; excellent landing facilities; aeromarine *Santa Maria.*

Newburgh.—Latitude 41° 30′ N., longitude 74° 00′ W.

Seaplanes only; buoy placed in river by Chamber of Commerce.

Rye.—Latitude 40° 39′ N., longitude 73° 41′ W.

No data.

Tupper Lake.—Latitude 44° 13′ N., longitude 74° 28′ W.

Osley Farm Field; 500 by 1,500 feet; good, fenced, along road.

(To be concluded)

EXPERIMENTAL STUDY OF HABITUATION TO ROTATION

CAN you think of rats—such vermin as rats—serving any good end to aviation?

Science says, "Yes!"

Some of those men who delve into the nooks and crannies and by-paths of the unknown things of life—men whom we call Scientists—have been experimenting on rats in order to add to our knowledge. They have learned much about the most desirable foods for human beings, for instance, from such experiments. And from other kinds of tests already made on rats they have discovered a number of facts that relate to the science of flying. For two years Professor Madison Bentley has conducted elaborate experiments on rats in rotation for the purpose of studying the effect of an animal becoming accustomed to turning around completely on an axis. Rats have been born in this process of rotation. Among the things Professor Bentley has found out is that certain tendencies toward loss of origin through the ear can be inherited. By orientation scientists mean the process by which direction is ascertained.

It is easy to recognize the value of such investigations as those concerned with the materials that go into the making of aircraft, the development of a reliable engine that will use a low grade fuel, or the determination of forces on an aeroplane, or of the interference effects of the structural members.

But few people realize that a small part of the inner ear has much to do with seasickness, and that this same portion of the ear effects the ability of a man to handle an aeroplane or airship.

Since the close of the war the National Research Council has had several projects centering on the studying of human factors in flying, involving behavioristic experiments on man and animals; anatomical, physiological and psychological studies of the functions of the ear and associated eye movements; the writing of a history; and the collection of a complete bibliography on the subject. Last year the workers in this field came together and organized themselves into a committee on Vestibular Research for the purpose of encouraging and co-ordinating work in this field. This committee has formulated a project on "The Experimental Study of Habituation to Rotation," which has been approved by the National Research Council. This project forms a natural nucleus around which may be gathered data from field experience, clinical records of fliers, and facts from laboratory experiments bearing on the subject in such a way as to favor a critical analysis of the situation and lay the foundations for both theory and practice.

The project will be administered by an executive committee, at the present time composed of Dr. J. Gordon Wilson, Chairman, Dr. Raymond Dodge, and Dr. F. H. Pike, in co-operation with the Chairman of the Division of Biology and Agriculture, Medical Sciences and Anthropology and Psychology in the National Research Council.

Dr. Dodge has made himself the outstanding authority on the measurement of eye movements as influenced by orientation through the ear, and it is believed that under his direction there will open up a large field of practical work which can be done to great advantage with a newly designed instrument for use in the study of the balancing power of aviators by photographical methods. Dr. Pike has made valuable contribution to brain anatomy bearing on the relation of the sensory mechanisms in the labyrinth to the sensory mechanism of sight and touch, giving us a new point of view in regard to the function of the ear in conjunction with the visual and tactical sense of orientation in flying. This opens up an entirely new approach to the practical investigation of fitness for flying, and should be followed up both by anatomical studies and by practical tests on flyers. Other scientific men on the committee include Dr. Irving Hardesty, who has undertaken to examine microscopically the Bentley rats, and to construct norms as a basis of comparison for future study of modifications in the air; Dr. S. S. Maxwell, who has made notable contributions to the study of anatomical conditions of orientation through the ear by studies on the shovel-nosed ray and other animals, which present unusually favorable conditions for the investigations of these phenomena; Dr. George L. Streeter, who is engaged in embryological studies of the development of the ear with particular reference to the structural conditions for orientation in flying; Dr. Knight Dunlap, who has equipped a laboratory in Johns Hopkins University at great expense specifically for the investigation of the behavior of human beings under conditions involved in flying; Dr. J. Gordon Wilson, who is now conducting investigations on hearing and the anatomy of this function; Dr. Percy W. Cobb, who has been active on the practical side of the question; Dr. W. H. Wilmer, who did such active work during the war and has been instrumental in securing the cooperation of investigators with reference to the organization of investigations on actual flyers, and Drs. L. R. Jones, V. C. Vaughan, C. E. Seashore, Chairmen of the Divisions of Biology and Agriculture, Medical Sciences, and Anthropology and Psychology of the National Research Council. The last three are ex-officio members of the committee, Dr. Seashore being its chairman.

The air service of the army is giving its active cooperation to the investigators through this special committee. Major Bane, Chief of the Engineering Division of the Air Service, has recently stated that a proper figure for research for experimentation in aeronautics would be ten million dollars annually. "There is no better economy than scientific research," he says. He has chiefly in mind of course research in machinery and materials, but what about the human in the aeroplane? The National Research Council is seeking to find some people who will be interested enough in this fundamental research as to favorable conditions in the aviator to provide not less than $25,000 covering the research investigations of this committee during the period of two years.

NOTES ON PROPELLER DESIGN—II

The Distribution of Thrust Over a Propeller Blade

By MAX M. MUNK

Technical Note National Advisory Committee for Aeronautics

Summary

THE best distribution of the thrust over the length of the propeller blade is investigated, taking into account chiefly the slip stream loss and the friction between the blades and the air.

The energy losses of the propeller depend noticeably on the distribution of the thrust over the length of the blades, and the losses can be diminished by a favorable distribution. The two induced losses of smaller importance, the loss due to the finite number of blades and the loss due to the rotation of the slip stream, call for a gradual decrease of the thrust per unit of propeller disc area towards the inner and outer end of the blades. Near the center the thrust is naturally less dense, and hence the loss from rotation is generally kept reasonably small without special effort of the designer and no further improvement is here possible. The breadth of the blades, however, is not always tapered towards the tips as much as would be desirable in order to keep small the loss due to the finite number of blades. It is true, the actual thrust distribution is almost as favorable in spite of it and the density of thrust always decreases properly, because it is physically impossible for a wing to produce a finite density of lift quite close to its end. Still the wing works then under less favorable conditions and with smaller efficiency, and the weight of the propeller and the centrifugal force is unnecessarily great too. Now, the following investigation will show that a gradual decrease of the density of thrust towards the ends is also desirable for other reasons. It is sufficient therefore to keep in mind that the wing tips have to be round, and to consider in the following investigation only the two chief energy losses, the energy absorbed by the air friction and the slip stream loss.

A small variation of the distribution of the thrust hardly changes noticeably the entire loss, especially if the distribution is already close to the best distribution. Hence the problem is less the exact determination of the best distribution of thrust than the derivation of a simple expression which gives quickly an idea as to how the thrust has to be arranged.

The conditions are quite different from those for ordinary wings. There, the inductive losses form a much greater part of the entire losses, and the other part, that is the loss of friction, does not depend on the distribution of the lift at all. Hence, with ordinary wings the distribution of the lift is determined by the consideration of the induced drag exclusively. With the propeller, however, the friction is the dominant part, and both, not only the slip stream loss but the loss of friction too, depend on the distribution of the thrust, for the velocity of the blade elements relative to the air is variable and greater at greater distance from the axis. And whether the ratio lift/drag be constant or not, the ratio of the useful work done by the lift to the energy absorbed by the drag is quite different from it and certainly not constant in general. The useful work is done in the direction of the constant velocity of flight, but the friction is multiplied by the relative velocity of the blade element and the loss is the smaller the smaller the relative velocity is. Therefore the consideration of the friction alone calls for a great density of the thrust near the center. The slip stream loss alone however calls for constant density of the thrust. Hence the smallest loss occurs at a compromise, that is, that the thrust is neither concentrated near the center nor distributed uniformly, but that the density of thrust decreases uniformly towards the outside.

A short calculation will be sufficient to give numerical information on the desirable decrease. Let C_P denote the density of the thrust per unit of the disc area divided by the dynamical pressure of the velocity of flight, that is

$$C_P = \frac{dT}{\dfrac{V^2 \rho\, df}{2}}$$

where dT denotes the infinitesimal thrust acting on the small area df of the propeller disc. C_P may be assumed to be small, say up to .50. Then the slip stream loss originated by this thrust is approximately ¼ C_P multiplied by the useful work done by the same element of thrust. The density of drag measured in the same way is $C_P\, C_D/C_L$ and the work absorbed by this drag is $C_D/C_L\; v/V$ times the useful work, where v denotes the velocity of the blade element relative to the air and V the velocity of flight. For simplicity's sake, I will replace the velocity v by the tangential velocity of the blade element, which is somewhat smaller but not so much that it will greatly injure the final result.

The problem can now be stated in the following way. Let r denote the radius of the blade element, that is, its distance from the axis. The entire thrust is easily found to be

$$(1) \qquad T = 2\pi q \int_0^{D/2} C_P\, r\, dr$$

The slip stream loss for the path of length 1 of the aeroplane can be taken as

$$(2) \qquad 2\pi q \tfrac{1}{4} \int_0^{D/2} C_P^2\, r\, dr$$

The energy absorbed by the friction during the same time is

$$(3) \qquad \frac{(2\pi)^2 q\, n}{V} \int_0^{D/2} \frac{C_D}{C_L} C_P\, r^2\, dr$$

The Coefficient of thrust density C_P variable along the length of the blade, is to be determined in such a way that for a given thrust (1) the sum of the two losses (2) and (3) becomes a minimum.

The solution is extremely easy. It can be seen that by transferring an element of thrust from one place to another the entire loss must not be changed, nor the entire thrust, and hence the ratio of the local change of loss to the change of thrust must be equal to a constant, say λ. The equation which determines the desired function is therefore

$$\delta\,(\lambda\,(1) + (2) + (3)\,) = 0$$

where δ means that the variation originated by any variation of C_P as to form. That is the same condition as if

$$2\pi q \int_0^{D/2} [\tfrac{1}{4} C_P^2\, r + \frac{2\pi n}{V} \frac{C_D}{C_L} C_P\, r^2 + \lambda\, C_P\, r]\, dr$$

is to be made a minimum. The variation is proportional to the integral over

$$\tfrac{1}{2} C_P\, r + \frac{2\pi n}{V} \frac{C_D}{C_L} r^2 + \lambda\, r = 0$$

which then has to be zero at every point r. Hence the solution of the problem is

$$(4) \qquad C_P = 2\lambda - 4 \frac{\pi n}{V} \frac{C_D}{C_L} r$$

It shows, as was to be expected, that the thrust density has to be constant only if the drag coefficient of friction $C_D = O$. But if the friction is taken into account, it is not constant but has to decrease towards the outside. The simplifying assumptions make it appear as a linear function of the radius, and that is just what we wanted, and exactly enough. It remains only to determine the value of the constant from the condition that the entire thrust has a particular value in order to obtain the final expression for the density of thrust. By substituting equation (4) in equation (1) it appears that

$$T = 2\pi q \int_0^{D/2} (2\lambda - \frac{4\pi n}{V} \frac{C_D}{C_L} r)\, r\, dr$$

i. e.,

$$T = 2\pi q \lambda \frac{D^2}{4} - \pi q \frac{\pi n}{3V} \frac{C_L}{C_L} D^3,$$

Hence

$$2\lambda = \frac{T}{\dfrac{D^2 \pi q}{4}} \frac{4}{3} \frac{C_D}{C_L} \cdot \frac{\pi n D}{V}$$

and finally,

$$C_P = \frac{T}{\dfrac{D^2 \pi q}{4}} + \frac{4}{3} \frac{C_D}{C_L} \frac{\pi n D}{V} - 2 \frac{C_D}{C_L} \frac{\pi n \,.\, 2r}{V}$$

Digitized by Google

At a radius 2-3 of the greatest radius, the thrust has the mean density, the same that it had to have without friction. At the blade tips, the density has to be

$$(5) \qquad \frac{T}{D^2 \frac{\pi}{4} q} - \frac{2}{3} \frac{C_D}{C_L} \frac{\pi n D}{V}$$

This expression can become negative. But then one essential assumption for the proceeding is no longer valid C_L/C_D is no longer constant but changes its sign. For this reason a negative thrust appears uneconomical in accordance with what everybody expects. Equation (5) becoming negative rather indicates that the diameter has reached its most economical value. This appears, then, to be

$$D^2 = \frac{T V}{n q} \frac{C_L}{C_D} \frac{6}{\pi^2}$$

Let us see now by means of an example, what the derived formulas give for usual conditions. They will give different results for the same propeller under different conditions of flight a reason more why to confine the calculation to a moderate exactness conveniently to obtain.

Illustration:

Diameter 9 ft., that is, disc area 63.5 sq. ft.
n 25 revolutions per second, that is n D = 706 ft/sec.
Thrust 400 lbs.
V 100 mi/hr.
C_L/C_D 22
q 25 lbs/sq. ft. dynamical pressure of flight.

$$D^2 = \frac{400 \cdot 100 \cdot 1.47 \cdot 22.6}{25 \cdot 25 \pi^2} = 1260 \text{ ft}^2.$$

$$D = 10.6 \text{ ft.}$$

That is pretty near to the actual diameter. However, the conditions of great velocity are favorable for a small economical diameter. Suppose on the other hand the velocity of the same propeller to be 60 mi/hr. only and the thrust to be 575 lbs. The dynamical pressure q may be 10 lbs/sq. ft.

Now,

$$D^2 = \frac{575 \cdot 60 \cdot 1.47 \cdot 22.6}{10 \cdot 25 \pi^2} = 2700 \text{ ft}^2.$$

$$D = 14 \text{ ft.}$$

Even in this case, the diameter results only 14 ft., which indicates that the improvement theoretically possible cannot be exceedingly great.

In the first case the mean value of C_P appears .252 and C_P at the blade tip has to be .106. The mean value agrees with the desired value at 2/3 of the radius as always. That is a rather great variability, which corresponds to the fact that the diameter is only slightly smaller than the most economical diameter. In the second example, the mean value of C_P is .90. This is comparatively high and in consequence of it the developed formulas give too large a diameter, for the factor .25 for the induced loss is too high for large values of C_P. Paying no attention to this, the coefficient at the blade tips appears .658. The density is much more constant now, according to the greater predominance of the slip stream loss.

The results obtained are only approximate. The formula for the diameter is not to be considered as a literal prescription. The weight of the propeller is not considered nor the resulting tip velocity, which cannot be increased without limit. Besides, the diameter is more often determined by the general lay-out of the aeroplane. The formula is only to show whether an increase of the diameter means an improvement at all, and to give an indication how much.

OFFICERS

JOSEPH A. STEINMETZ, *President*
1421 Chestnut St., Philadelphia
WILLIAM H. SHEAHAN, *1st Vice-Pres.*
HENRY F. BAMBERGER, *2nd Vice-Pres.*

AERO CLUB PENNSYLVANIA

DIRECTORS

CHARLES L. HOWER
GEORGE S. IRELAND
WALLACE KELLETT
FRANK A. L. LEAHY
ROY G. MILLER
D. J. SPENCE, JR.
A. STANLEY TRUSCOTT

The stated monthly meeting of the Club was held at the Engineers' Club on the evening of April 24th. It is a source of much gratification to note that the meetings are being more largely attended than ever in the history of the organization. This is undoubtedly due to the excellent program of the meetings and the interesting lectures which the committee on entertainment provide.

Mr. H. L. Goehde, Managing Director of the Municipal Exposition, gave an interesting talk on the Aero Meet which he is planning for Philadelphia, to be held the latter part of May. Liberal prizes and trophies for the events will be offered and if the response is sufficient to guarantee the meet same will be held under the auspices of the Aero Club of Pennsylvania, the officials of which will act as judges for the races and contests.

Mr. Stephen H. Noyes, of the city Bureau of Surveys addressed the meeting on the subject of Municipal Landing Fields and invited the views of the members as to location and proper size of same. Mr. Noyes secured a great deal of data which he proposed to submit to City Council and it is felt that very soon Philadelphia will fall in line with the other progressive cities which have visioned the future and provided air ports for the winged ships of the air.

In connection with the above, the Club is in receipt of blue prints and photographs from the Department of Commerce, Bureau of Standards, Washington, in which Mr. Arthur Halstead, Chairman of Subcommittee on Airdromes and Traffic Rules, invites the Club to submit their comments and criticism of the sizes, markings and dimension of the fields as arrived at by the subcommittee on March 10th.

President Steinmetz has written, in the name of the Club to fully a dozen or more senators. Making an earnest appeal to their patriotic spirit to support the budget for Aviation Research with particular reference to the opportunities of the McCook Field for the reason that aviation research work is the essential working out of commercial aeroplane safety. The letter is a prayer that the appropriation agreement of $3,250,000 for the fiscal year 1922-23 shall stand without any reduction.

Lieutenant Ralph M. Haynes, who served with the British in the World War and who is known as a stunt flier, claims he has established a world's record for tail spinning, as the result of a flight at the Bergdoll Field, Manoa, Pa., on April 24th.

He fell between 9,500 and 9,700 feet in the tail spin. It is claimed the best previous record is 8,500 feet, made at Daytona Beach, Fla., last fall. Haynes carried A. O. Gillette with him as an observer. Gillette is also a stunt flier. They took the plane up to an altitude of 11,500 feet, but could not ascend further because the pump froze. They dropped from that level and righted the plane without difficulty about 2,000 feet from the ground.

The regular monthly meeting for April was held at the Engineers' Club on the evening of April 26th. The members of the Club were thus given the opportunity of a joint session with the Society of American Military Engineers. The speaker of the evening was Major P. E. Van Nostrand of the Training and War Plans Division of the Army Air Service and the topic of the lecture was "Airships and Helium Gas."

The many lantern slides and motion pictures with which the lecture was illustrated were highly interesting and instructive.

It was announced that the Army Air Service is soon to take a series of photographs of Philadelphia and surrounding territory, in co-operation with the joint committee of the Chamber of Commerce and Aero Club of Pennsylvania, for the purpose of a selection of Air Fields for the Sesqui-Centennial of 1926.

The Aero Club of America has appointed Major Charles J. Biddle, Mr. Wallace Kellet and President Steinmetz of the Club as representatives to attend the session of the Academy of Political and Social Science, meeting in Philadelphia, May 12th and 13th.

W. H. SHEAHAN,
1st Vice-President.

THE VERSATILE AEROPLANE

A great deal has already been written about the versatility of the aeroplane, both in time of war and in time of peace. As an instrument of warfare the aeroplane is a most potent force. The great World War has amply demonstrated this, and the contention that aircraft serve as a first line of offense or defense was proven beyond question during the maneuvers last year at Langley Field, Va., when a number of modern type warships were sent to their watery graves as a result of the accuracy our airmen had acquired in dropping high explosive bombs. As a peace time utility, however, the possibilities of the aeroplane are without limit. Many uses have already been found for it, aside from its principal ues as a means of rapid transportation.

The aeroplane is an engine of destruction in time of war, but it appears to be just the reverse in time of peace. The world is just beginning to realize what a great boon to mankind it really is. For the past several years the Army Air Service has been co-operating with the Forestry Service in an endeavor to suppress the great number of forest fires occurring annually in the vast forested areas of our Great Northwest and in California. Using aeroplanes as a means of patrolling these forests, the observers were able to discover fires practically at their inception, and the prompt reporting of same by radio to headquarters enabled the fire fighters to institute prompt measures to combat them. Thus, the aeroplane has played a most prominent part in conserving the timber resources of the country, and has thereby saved the government vast sums of money.

Fire, however, is not the only destructive force that continually threatens the existence of our forests and orchards. The insect pest is also a power to be reckoned with. Last summer a grove of Catalpa trees near Troy, Ohio, was practically defoliated by the ravages of caterpillars. Here, again, the aeroplane came to the rescue. Flying over this grove and spilling arsenate of lead powder from a hopper attached to the side of the fuselage, the aeroplane accomplished in one minute what could hardly have been accomplished with twenty of the most powerful liquid spraying machines. And the experiment was a pronounced success, the official report on same stating that practically all the insects were exterminated.

The sealing industry, heretofore a rather fluctuating, hit-or-miss sort of a business, and which, for this reason, has been steadily and persistently declining for several past decades, bids fair to recuperate under the ministrations of "Doctor Aeroplane." By reason of the fact that there was no system of intelligence to guide the sealing fleet in its movements, there was always a likelihood that during the night an ice floe carrying the main herd of seals would drift silently by a few miles away and be far over the horizon before the sealers realized the unkind trick Dame Nature played upon them. The occasions upon which the main herd have been missed in this manner have been numerous, and under such circumstances the disappointed sealers were forced to rest content with such crumbs in the form of detached masses of ice carrying a few seals as happened to come their way. The coming of the seal aeroplane has changed all this. Seeking for seal-laden drift ice and maintaining constant wireless communication with the sealing fleet is identical with the spying out of the countryside for the movement of troops in war. The reliability of the flying machine, combined with its radius of action, has rendered it indispensable to the industry.

Out on the Pacific Coast fishermen have utilized the aeroplane in locating schools of fish and leading the boats to large hauls.

As regards the subject of surveying and map making, the aeroplane has already established itself as a practical means of securing quickly, cheaply and accurately, information which can be put to a wide variety of uses in engineering practice. Added to this is the ability of the aeroplane to cover territory inaccessible on foot. Aeroplane photography offers extremely interesting possibilities.

And now we come to a subject that intimately concerns the farmer. Last summer the Bureau of Plant Industry, Department of Agriculture, conducted in a very limited way experiments along the line of collecting from the upper air certain parasites which have been causing different plant diseases. The results they have achieved justify their opinion that a great deal can be learned from a study of the different spores which can thus be collected. The most destruction of this fungi is the black stem rust of wheat, oats, barley, rye and many grasses. An idea of the destructiveness of this parasite may be gained from the fact that in 1916 it caused the destruction of over 200,000,000 bushels of wheat in the United States and Canada—not a very pleasant thing to contemplate either by the farmer or the consumer. It is known that this parasite survives the winter in the north on the common barberry bush which has been used so extensively for hedges. Steps have therefore been taken to eradicate this particular plant on this account. The theory is advanced that these spores are developed in the south and are carried north into the wheat regions by the air currents. Dr. Stakman of the Bureau of Plant Industry, Department of Agriculture, under the direct supervision of Dr. Kellermann, Associate Chief of the Bureau of Plant Industry, in co-operation with representatives of the Engineering Division at McCook Field, Dayton, Ohio, is conducting certain experiments in this connection, and there is now being designed an efficient type of spore trap which will contain several common laboratory slides, the faces of which slides will be covered with a gelatinous matter or vaseline. These spore traps will be placed on aeroplanes and will be so arranged that different slides may be exposed at different elevations in the air. It is anticipated that the air blowing against these slides will result in there being collected on them whatever fungi there may be present in the air in that particular region. A simple laboratory test will serve to identify the various classes of fungi spores which may be collected.

Representatives of the Department of Agriculture will conduct these tests during the spring and summer at Kelly Field, San Antonio, Texas; Chanute Field, Rantoul, Ill.; Fort Riley, Kansas; Post Field, Fort Sill, Okla.; and Camp Knox, Ky. These spore traps will be installed on a great number of aeroplanes during the course of their numerous flights, and a careful record will be kept of the results obtained. At the end of the season a compilation of the results will enable the Bureau of Plant Industry in Washington to arrive at some definite conclusion in regard to this plant disease, and the Department of Agriculture may then be able to devise the neessary measures to combat, if not entirely eradicate, this highly destructive plant disease.

Just recently aeroplane pilots from Carlstrom Field, Arcadia, Fla., co-operated with the well known scientist, Dr. David Todd, Professor of Astronomy and Navigation, in a rather interesting experiment at Miami, Fla. Moving pictures were taken of the sun from an aeroplane at altitudes of 16,000 and 17,000 feet. The idea of taking the pictures from such altitudes was to get away from the dust particles in the atmosphere near the earth's surface. Professor Todd expects to gather some very interesting data from these films.

The other day the Netherlands Aircraft Mfg. Co. sent us a communication stating that it is reported from Holland that exceptionally severe weather would have imposed great hardships upon the inhabitants of the many islands which lie to the north of the Dutch mainland were it not for the timely assistance rendered by the big Fokker aeroplanes of the Royal Dutch Air Service Company. All boat traffic having ceased owing to the ice, the aeroplanes were used to deliver large quantities of food and other supplies to the islands.

The foregoing enumerates only a few of the many uses which have been made of the aeroplane, which can be truly classed as the most wonderful invention of the age. Can anyone stretch his imagination far enough to say to what further use the versatile aeroplane will be put in the near future? Certainly, the aeroplane has come to stay, but it deserves far greater recognition and much better treatment than that which has so far been accorded it.

AEROPLANES USED IN EXPERIMENTAL WORK IN THE STUDY OF RUST SPORES

E. H. Ostrom, field assistant in cereal investigation of the U. S. department of agriculture, has arrived in Lawton, Okla., for the purpose of conducting a series of experiments requiring the use of aeroplanes. Mr. Ostrom is a graduate of the College of Agriculture of the University of Minnesota.

The war department is cooperating with the department of agriculture in these experiments and in the work which he plans in this vicinity Mr. Ostrom is receiving cooperation from Post Field officials.

Mr. Ostrom explains the nature of the experiments, which will be of incalculable value to agriculturists, in the following:

"As long as 200 years ago plant diseases have been traced from their source for a distance of several miles. It is therefore an established fact that plant diseases travel from one field to another carried by the wind, also that diseases which show up in some small area of the county in time spread so as to cover the whole of that county.

"It is also considered probable that it may travel to adjoining states or even further, but definite data is lacking.

"The black stem rust and other rusts are fungi, a form of plant life, very much re-

Where Wright Aeronautical Engines Are Made

ACREAGE Approximately 7 acres, located on Main Line of Erie Railroad.

AREA 90,000 square feet.

DESCRIPTION Four floors, size 75 ft. by 300 ft. Concrete and steel heavy mill type construction, 250 pounds per square foot loading.

EQUIPMENT The plant is equipped at present to produce, and is producing approximately 300 engines per year, with spare parts therefor, and has ample capacity in addition to provide adequately for all spare part requirements for all types of engines previously produced. The equipment of the plant provides for the complete manufacture of various type engines produced, including bronze and aluminum castings, except bar steel and drop forgings. The capacity of the present plant could be expanded to produce engines at the rate of five per day in the present building. In an emergency the present acreage would allow of enough additional buildings and equipment being provided within six to eight months to produce engines of any one type in quantities of at least 25 per day.

The plant has employed during the past year an average of 450 people, which includes a complete Engineering Department and Experimental Shop.

WRIGHT AERONAUTICAL CORPORATION
Paterson, New Jersey, U. S. A.

sembling bread mould. The reproductive units, which correspond to seeds of plants, are known as spores. These spores are too small to be seen with the naked eye, but when grouped together by the thousands as they are found on the wheat plant, they are visible as a pustule of rust.

"When the rust matures the spores are blown off and picked up by the wind and carried to other fields, thus spreading the disease. They alight on the growing grain, germinate and get inside the plant tissues, growing and branching so as to form a good root system; then as soon as weather conditions are favorable for the development of the disease, they grow rapidly, mature and burst through the epidermis, and we have rust on the plant.

"Lice do not have good pickings on a starving dog. Neither does the rust thrive on a drought-stricken wheat plant. When the wheat plant is growing most vigorously, when the sap is rushing up to nourish and fill the wheat head, then the rust develops most rapidly, sucking the sap which should fill the head. The result is light bundles, low yield and shriveled kernels.

"The black stem rust presents a problem. To fight it we must know definitely how and when it travels. In the states north of Kansas, Missouri and Tennessee, the common or Barberry bush rusts early in the spring and spreads the black rust in its own territory. Barberry bushes do not rust in the south. In Texas and Mexico, the rust lives over winter on the winter wheat and on grasses, and the prevailing winds spread it around.

"The Daily Oklahoman on Monday, April 24, contains an article which creates the impression that army planes are to be used in spraying or dusting the wheat fields. This is incorrect, for there is no such intention.

"What we want is to determine how high the spores are carried upwards and at what altitudes they are most abundant; to learn at what time they appear in the air in different parts of the country; to find out the reaction of the spores to temperature, humidity, precipitation, ascending and descending air currents, velocity and direction of prevailing winds and any other meteorological data which may become available.

"Spore traps have been designed to catch these spores on glass slides coated with a thin layer of vaseline to which they stick.

"One or more altitude flights are planned during which a standardized thermometer will be used to record the temperatures at the various altitudes at which the exposures are made.

"Major Lohman, assistant commandant of Post Field, in explaining the whole hearted interest of the air service in these experiments said: 'You have my permission to fly from 8 a. m. to 4 p.m. every day in the week.' This gives me the opportunity to choose the most desirable time for each flight.

"Cross-country flights will be made to such cities as Liberal, Kan., Denver, Colo., Lincoln, Neb., St. Louis, Mo., Dallas, Tex., etc. Slides are to be exposed at points separated about 50 to 100 miles along the route, as well as at each of the destinations. This, then, permits of a fairly representative area being covered.

"After exposure these slides will be sent to the Minnesota Agricultural Experiment station for examination. Messrs. Christensen and Lambert, pathologists, at Minnesota, are to make the spore counts and will also make attempts to germinate the spores.

"Mr. G. C. Curran, state leader for Barberry eradication work in Illinois, will make flights from Chanute Field, and Wallace Butler, botanist at San Antonio, from Kelly Field.

"Dr. E. C. Stakman, chief of the division of plant pathology at Minnesota, is the guiding genius for the whole work."

Back Pay for Former Flying Cadet Awarded

The Court of Claims of the United States made a decision on February 27, 1922, stating that Nelson W. Rider, formerly flying cadet, United States Army, was entitled to $306.82 back pay, incurred when the pay of flying cadets was cut from $100 per month with 50 percent increase for flight duty to $33 per month plus 50 percent thereon for flight duty. This cut was made about the first of July, 1918.

Following is an extract from the decision of the Court of Claims: "The Government contends that the provision of the act of June 15, 1917, which established the pay of the plaintiff at $100 per month expired with the expiration of the appropriations set forth in the act. We are of the opinion that this contention is not tenable because of the provisions of the act of July 24, 1917, and of the act of July 9, 1918, which latter act makes available the appropriations of the act of July 24, 1917, and of the appropriations of the act of May 12, 1917, until June 30, 1919. Nor does it anywhere appear that there was any intention to repeal the provisions fixing the pay of enlisted men in training for officers of the Reserve Corps. It is hardly possible to conceive that Congress would at the height of the emergency, while the war was going on, reduce the pay which had been held forth as an inducement to the young men of the country to enter into training for officers in the Reserve Corps."

The Government has 90 days from February 27, 1922, in which to make an appeal. If this is not done within the allotted time, the decision holds.

Aerial Age has received several inquiries as to whether it will be necessary to file suit against the Government and obtain the services of an attorney to get back pay. This is not necessary. Former flying cadets should file their claims with the Comptroller General, War Department, Washington, D. C., and if the decision is upheld they should receive back pay due them.

Reserve Corps Activities in Oklahoma

Prior to the arrival of an Air Service officer for duty with the 95th Division, U. S. Army, the headquarters of which is Oklahoma City, Major J. C. King, Cavalry, A. C. of S. (G-1), began the organization of the 320th Squadron (Observation) 95th Division. At the present time Captain Louis D. Abney, A. S., O. R. C., Oklahoma City, the senior officer of the squadron, is due for promotion, and will, by virtue of his rank and experience, command the squadron.

In order to get the "right man in the right place" in the squadron, the Air Service officer with the Division is getting from all listed Air Service Reserve officers in his territory a tabulated statement of their air experience. It was found that this information was not definite enough under the heading "Chronological Statement of Military Service" on the reserve officers' qualification cards.

The headquarters of the Air Service of the 95th Division is at Muskogee, where the Air Service officer with the Division (now at Oklahoma City) will be located after April 1st. The headquarters of the 320th Squadron is at Oklahoma City.

It may be of interest to set forth the allocation of Air Service units to the State of Oklahoma:

The *first priority* for organization in the State of Oklahoma is:

Division Troops
95th Division, A. S. Hqrs......Muskogee
320th Squadron (Obs.)....Oklahoma City
320th Photo Section..............Tulsa
Branch Intelligence Office, A. S., 95th Div., not allocated.

Second Priority:
Army Troops, III Field Army
321st Air Service Attack Group, Hqrs., Enid
472nd Air Service Attack Squadron, Enid
473rd Air Service Attack Squadron, Enid
474th Air Service Attack Squadron, Enid
350th Air Park ....Enid
431st Photo Section................Enid

Third Priority:
XVIIIth Corps Troops—VI Feld Army.
365th Squadron (Obs.) ....Tulsa
365th Photo Section......Oklahoma City
329th Balloon Company...Oklahoma City
108th Communications Section ....Oklahoma City

As soon as the Division Air Service is completely organized and capable of functioning in case of mobilization for an emergency, the second priority organization, and then the third will be started.

Outside of the regular Air Service garrison at Post Field, there are no other Federal Air Service activities in the State beyond what has been above mentioned.

The Aviation Committee of the Chamber of Commerce of Oklahoma City is a wide-awake organization. They are actively on the lookout for better airdrome facilities than now possessed at Needham Field. They realize the great future of aviation and are anxious to have Oklahoma City on the air map.

This same committee is forming the nucleus of a National Guard Squadron for the State, with the idea that they may get flying training, which they must have before being eligible for appointment as Reserve Officers.

Development of Model Airway

Under instructions recently received from the Chief of Air Service, First Lieutenant Clarence E. Crumrine, A. S., has been detailed on duty to investigate the route of the Model Airway from Mitchel Field, L. I., New York, to Pine Valley Field, N. J. This work includes the making of standard sketches and the completion of questionnaires on all intermediate fields, together with the taking of oblique photographs. These fields and following points are being investigated, sketched and photographed:

Valley Stream, L. I.; Belmont Park, L. I.; Sheepshead Bay, New Dorp, Staten Island; Freehold, New Jersey: Prospertown, New Jersey; Camp Dix, New Jersey; Medford, New Jersey; Sandy Hook, New Jersey.

Work on the development of this air route has already begun. It has been delayed due to inclement weather but will be now pushed to rapid completion.

Progress of the Air Service Mechanics School

The Air Service Mechanics School at Chanute Field, Rantoul, Ill., is functioning in every department. There are now 496 students actually undergoing instruction, and 225 awaiting instruction. The first class of men who were enlisted in the recent recruiting campaign will be graduated on May 12, 1922. It will consist of twelve armorers. Following this comes a class of five blacksmiths, who will complete the course on May 26th, and the following classes on June 9, 1922: Armorers, 12; fabric workers, 4; mechanics, airplane, 13; mechanics, airplane engine, 14; mechanics, auto, 14; machinists, 5.

The next class will graduate on June 26, 1922 and classes will follow throughout the year at periods of two weeks.

NAVAL and MILITARY AERONAUTICS

Night Flying in the Philippines

Lieut. R. Baez, Jr., gave the garrison at Clark Field, Pampanga, P. I., and not a few visitors, a thrill on Friday night, February 17th, when he made a night flight for the purpose of testing out the new flood lights recently installed on the hangars for emergency use. Lieut. Baez remained in the air for an hour, during which time he flew over the encampment of troops located several miles northeast of the field and Camp Stotsenburg proper. A perfect landing was effected, but due to the rough field a shock absorber was broken, without mishap, however.

Agricultural Experiments at Kelly Field

Prof. J. G. Butler, of the Department of Agriculture, made flights on March 27th and April 1st, from Kelly Field, with Lieut. F. P. Booker as pilot, in connection with some experiments he is conducting with a view to determining the origin of the spore of wheat rust in this country. The flight on March 27th was made in a DH4-B and the one on April 1st in a JN6H. It is the belief of the officials of the Agricultural Department that the spore of this parasite travels in the upper air from Mexico, and possibly Central and South America. Plates with a mucus substance on one side are mounted on a rack on the wing, and by shutter arrangement are exposed from a control in the rear seat, whenever desired. Exposures were made at every 500 feet up to 3,500 feet with much success. In this experiment the JN6H was more satisfactory than the DH4B, the air stream of which prevented the shutters from closing again.

Aviation Activities in Massachusetts

There is every likelihood that a landing field will be established in the City of Boston, if the efforts of a progressive organization like the 101st Aero Squadron, Massachusetts National Guard, count for anything. This squadron was federally recognized November 18, 1921, and was inspected for permanent federal recognition March 3, 1922. Rooms have been assigned to house the squadron at the South Armory, Boston, and a drill period is held there every Friday night from 7:30 to 9:30 p. m. Some of the officers and non-coms give Monday evenings to squadron affairs, and spend other time at the armory also.

Of the commissioned personnel of the squadron, the following have been assigned to regular duties: Major Charles H. Woolley, Commanding Officer; 2nd Lt. L. E. Boutwell, Adjutant and Supply Officer; 2nd Lt. H. N. Carlson, Engineer Officer and Officer in Charge of Instruction.

The strength of the squadron on April 8th was 12 officers and 67 enlisted men. The officers enumerated above are the only ones so far assigned to special duties. Non-commissioned officers have been appointed to act as such until June 1st, when examinations will be held for permanent appointments.

Under the direction of Lieut. Carlson, a schedule of instruction has been prepared and closely followed. Assembly is at 8 p. m. About half of each period is given over to basic training, such as infantry drill on the armory floor. The remainder is devoted to technical training. The enlisted men have been divided into sections for technical training, each section pursuing its assigned specialty of rigging, engines, ordnance, etc. Usually, on alternate Fridays the sections meet as a whole for a group lecture, the squadron being especially fortunate in having secured the voluntary services of Prof. E. P. Warner, of the Dept. of Aeronautical Engineering, Massachusetts Institute of Technology, who is delivering regularly a series of lectures to them.

Aside from uniforms, office furniture, and a few items of school equipment, the organization is still unequipped to function as a squadron. Its requisitions for flying equipment may be approved, but deliveries must wait until the State provides an aerodrome. Until then the flying activities of the squadron will be confined to occasional hops by some of the officers in planes of the A. S. Detachment of Framingham.

The problem of securing a landing field and suitable housing facilities for its equipment is the chief concern of the squadron today. It has combined efforts with the Corps Area Headquarters, the Chamber of Commerce of Boston, and the various aero clubs and interested individuals who are behind a bill now before the State Legislature which provides for the construction of a municipal landing field in East Boston which is to be leased for a ten year period to the Federal government for a nominal rental, the field to be used jointly by military and civilian planes, though under Federal supervision. The bill specifies an expenditure by the State of $35,000.00 to level and prepare the runways. Ground adjacent to that leased to the Army is to be leased to civilian and commercial fliers for hangars and shops, and it is hoped that the establishment of this field will lead to the extension of the transcontinental Air Mail service from New York to Boston. The proposed field is within two miles of the Boston Post Office. This East Boston site has exceptionally favorable characteristics for a municipal aerodrome from the standpoint of convenience of location, freedom on all sides from obstructions, availability (the whole property is state-owned and at present is lying idle,) and its conspicuous position in the harbor making it easy to locate from the air. In addition, being surrounded on three sides by water, it will be available for seaplanes.

The landing field bill has been favorably reported by the Committee on Public Lands. It is now before the Joint Committee of Ways and Means. One hearing has been held. The latest advice concerning its progress in this Committee is to the effect that they are waitng for a definite proposal from the War Department stating exactly what the Army will furnish this aerodrome in the event that the bill is passed, and exactly what the cost will be to install and maintain hangars and shops, etc., for the National Guard. When the Committee receives more definite figures concerning the State's share of the expense, it will undoubtedly come to a decision on the bill. The present indications are against an early report in favor of the bill should the Committee find out that the State will have to spend much more than the $35,000 first asked for to be spent on the runways.

With regard to the social activities of the squadron, the Aero Club of Massachusetts gave a ball on February 24th, and donated half of the proceeds to the squadron fund. This donation amounted to $638.26, and some contributions by the officers added to this has given the squadron fund a good start. This fund has been tapped to pay for coffee mugs, books, extra clerical work, and small administrative expenses. It is expected that the splendid interest and morale so far manifested by the personnel will increase with the approach of summer weather and lead to more social activities such as help to weld the organization into a "regular" body fostering good fellowship and loyal pride in themselves and in the army.

Athletics of some sort, including a baseball team, are contemplated for early inauguration.

Airplane Formation Greets New Department Commander

In preparation for the arrival of the new Philippine Department Commander, Major W. M. Wright, who sailed from the States on the Transport *Thomas*, arrangements were made for an eleven-plane formation to escort the *Thomas* to her dock. Five planes were flown to Paranaque Beach, Manila, on the morning of March 3rd, the pilots of these planes being flown back to Clark Field in the afternoon by pilots from Camp Nichols. At 6:45 a. m., March 6th, a five-plane formation took off from Clark Field and flew to Manila Bay, where they were joined by the formation from Paranaque Beach. They flew to meet the *Thomas* and escorted her to the pier.

A Bombing Record at Aberdeen, Md.

The best bombing record for the Aberdeen Proving Grounds, Md., was made on April 6th, when, with First Lieut. Max F. Moyer, A. S., and Master Sergeant William F. Fitch, Air Service, as pilots, and Captain S. R. Stribbling, Ordnance Department, as bomber, a total of seven hits out of eight bombs dropped was recorded. The bombs were dropped from an altitude of 2,000 feet on the "Hard Surface," a concrete block, 200 feet by 200 feet. The eighth bomb missed the target by approximately two feet. During the week ending April 8th a total of 2,600 pounds of bombs were dropped from the Airship C-2 on the "Hard Surface".

Test of Sperry Gyro Compass

A special flight was made at the Aberdeen Proving Grounds on April 3rd with a Sperry Gyro compass. With Mr. J. A. Fitz, of the Sperry Company, conducting the test on the compass, a triangular course was flown from Aberdeen to Belair, to Havre de Grace and return to Aberdeen. The performance of the compass on this short run was very satisfactory.

FOREIGN NEWS

French Air Mail

In connection with the report on French commercial aviation activities published in Commerce Reports of January 23, 1922, recent figures are interesting as showing a considerable increase in the use of the aerial postal service between Toulouse and Casablanca. During October, 1921, 40,600 letters, weighing 1,560 lbs., were carried between the points named as against 24,850, weighing 870 lbs., in October, 1920. A saving of five days in transmission of mail accounts for the popularity of the air route. During the year ending September 30, 1921, the mail matter carried by this service consisted of 306,181 pieces out of a total of 351,742 pieces carried by all aerial routes between France and foreign countries. Of the figures given, the Paris-London service transported 28,534 pieces, the remainder being carried by the services from Paris to Brussels, Amsterdam, Prague and Warsaw.

Egyptian Air Mail

The aerial mail route established between Cairo and Bagdad has been extended to include Palestine. A regular fortnightly service will be maintained in each direction.

German Aeronautics

The Director of the "Aero Union," a German Aircraft Corporation, with headquarters in Berlin, which controls and operates the "Deutsche Luftreederei," a German Air Traffic Company, announced recently that his company has made arrangements to establish an aircraft factory near Pisa, Italy, and that the production of all-metal Duraluminum aeroplanes is expected in May or June, 1922. The raw material for these airplanes will be shipped from Germany and worked up and assembled in Italy by German and Italian workmen. The "Aero Union" was organized a few months ago, and is controlled by a combination of the "Allgemeine Elektricitats Gesellschaft" (the General Electric Company of Germany), the Hamburg-American shipping interests, and the Zeppelin Aircraft interests.

Announcement has also been made that the "Aero Union," in cooperation with the Russian Government, has organized a company under the name of "German Russian Air Transportation Company." The company hopes in the Spring of this year to organize a regular air service between Germany and Russia with passenger airplanes of the Russian Government, temporarily on the stretch between Konigsberg-Moscow, in close connection with the Berlin Evening Express and return. The preparations for this are being directed by German and Russian technical experts. The service will primarily be for the purpose of transmitting official courier mail matter from Berlin to Moscow and Moscow to Berlin, as well as passenger and light freight service.

Progress in England

The promotion of a great flying festival at the London Air Station, Croydon, is a matter that is engaging the attention of the Air Ministry, Aircraft Constructors, Aero Club, Aeronautical Society and Air League. The festival is to last a week, will probably take place early in 1923, and is being designed to fasten attention on flying in a way that has hitherto not been found possible. The main feature of the festival will be an exhibition of every type of modern flying machine, including, it is hoped, helicopters. Concurrently, an international congress on air problems will be held, and speed and duration tests organized and decided. An effort is also being made to arrange that the Royal Air Force annual pageant shall be held at Croydon during the week.

In order to speed up the delivery of goods to Paris from Manchester or other provincial towns in England, a night aeroplane service will shortly be inaugurated whereby parcels dispatched by passenger train after business hours from these towns will be collected by a special motor van from the London Railway Terminal between midnight and 1:00 a.m., and immediately thereafter put on board the night express leaving the London airdrome at 2:30 a.m., and scheduled to arrive at Paris at about 5:00 a.m. Upon arrival in Paris the goods will, by special arrangement, be passed through the French customs and delivered by motor van in Paris as soon as business houses are open. A similar arrangement is to be instituted in connection with goods from provincial towns in France consigned to London, an air express leaving Paris early in the morning and parcels sent from, say, Lyons or Lille, after business hours one evening will be delivered in London the following morning, or in Manchester or other towns by the afternoon.

The night expresses which are now being built will be equipped with instruments and navigation lights for night flying, and this, in conjunction with the illumination of the London to Paris Airway, soon to be completed, will make night flying a safe and regular operation.

With the opening on April 3rd of the new Paris-London Aerial Company, known as the Daimler Airway, the number of British companies operating regularly between London and Paris has been raised to three, the other two being the Instone Air Line and the Handley Page Co. The new company will use the latest type of D. H. machine, known as D. H. 44, and will run a daily service in each direction. There are also two French companies working on the route. Even at this time of the year a regular flow of passengers continues, most of them being American and English family parties on holiday.

Rotterdam-Copenhagen Service

According to FLIGHT (London) arrangements have been made for inaugurating an air mail service between Rotterdam and Copenhagen. The company which is to undertake the new service is stated to be Danish, although it is intended to use British machines and pilots. The plan is to have machines leaving Rotterdam in the morning, after the arrival of the night boat from London, and it is expected that they will be able to reach Copenhagen shortly after noon, so that the mails should be distributed early in the afternoon in that city. In the opposite direction machines will leave Copenhagen at 3:00 p.m., and will reach Rotterdam in time to connect with the night boat to London. Thus, instead of taking 72 hours, the mails between London and Copenhagen should do the journey in about 24 hours.

Netherland Activities

The Royal Aerial Navigation Co. of the Netherlands carried during 1921 a total of 1,548 metric tons of mail, 36,634 metric tons of freight and 1,674 passengers. The Amsterdam-London line accounted for more than half of the mail and merchandise, carrying 844 tons of the former and 24,875 tons of the latter. In 1921, 931 passengers traveled on the Amsterdam-Brussels-Paris line and 254 on the Rotterdam-Hamburg line. These figures indicate a marked increase over the 1920 volume of traffic, which totalled only 3 tons of mail, 22 tons of freight and 345 passengers.

French-Italian Race

The greatest of many attractions at the aviation meeting held at Nice this Spring was a speed contest between two of the fastest aeroplanes in the world. Sadi-Lecointe, the French champion, met Brack-Papa, the famous Italian flyer, the Frenchman being on a small, speedy Nieuport scout plane, while the Italian had a high-speed Fiat bombardment aeroplane driven by a Fiat 12-cylinder, 700-h.p. engine.

The two championa were very closely matched. At the outset of the aerial race Brack-Papa got a slight lead and maintained it to the end, for he covered the course on his Fiat in 9 min. 42 3/5 seconds, compared with 9 min. 50 seconds for Sadi-Lecointe's Nieuport. The speed of the planes was about 190 miles an hour.

Durban Aerodrome

The work of filling in and leveling the ground on the Eastern Vlei near Durban, set aside for an aerodrome, has now been completed, but nothing else has been done, and it will be left to private enterprise to concert the area into a suitable flying ground, reports the *Natal Mercury*. All the municipality was concerned with was the setting aside and levelling of the area. At present there does not seem much chance of a rush of applicants for accommodation, as there has been no flying in Natal for some time, but the Town Council were right in preparing an aerodrome, as commercial flying has come to stay, and in the near future South Africa will have to fall into line with other countries in adopting and encouraging aviation.

Germany Will Extend Commercial Air Lines

German commercial aviation circles are making extensive plans to resume and extend international air service when the Allies, as announced, remove their military control May 5. Prior to this the Germans could not establish international lines. Some companies evaded the interallied control by establishing companies in other countries, notably Holland.

A scheme has been perfected for a Berlin, Danzig, Kovno, Moscow line. Another German company plans to extend its service across Russia to Pekin this year. Inside of Germany there has been an increase recently in the number of air lines. The Hamburg-Amsterdam lines have been closed down, but toward the east there is the line to Stuttgart which was established recently. Airplane service between Munich and Constance has been resumed. There is a new line between Bremen and Dresden and during the summer aeroplane traffio between Berlin and Hamburg and north and Baltic resorts will be resumed. The Government is not now supporting commercial aviation, but German big industry stands behind German aviation.

Aircraft in Chinese War

The forces of Sun Yat Sen, head of the South Chinese Government at Canton, have captured the entire Southern Naval Squadron, it was stated in unofficial despatches published by the foreign and Chinese press.

The squadron captured, although containing some of the most important Chinese war vessels, amounts to little from a naval standpoint, authorities agree. The ships captured, reports stated, include the cruiser Hai Chi, the largest vessel in the Chinese Navy, but of only 4300 tons displacement; the cruiser Hai Chen, the gunboats Chu Yu, Yung Peng, Yu Chang, Yung Shan, Fei Ying and Yun Yan, the training ship Chao Ho and the transport Fu An.

The attack on the vessels which resulted in their surrender was carried out by aircraft in conjunction with South Chinese troops. The aircraft bombed the vessels in the Pearl River, twenty men being killed and thirty others wounded on board the cruiser Hai Chi in the initial attack, the reports state.

Later there was a further bombing attack on the vessels near Canton, in the Whampoa River, the Hai Chi and other craft surrendering.

(*Concluded from page* 219)

performance are taken to a laboratory, greatly enlarged for study, and then plotted on a single sheet so that a complete story of the particular flight or manoeuvre is ready for analysis.'

The instruments developed have been employed at the free flight laboratory of the National Advisory Committee for Aeronautics at Hampton, Va., by Test Pilot Thomas Carroll, in studying ordinary and "stunting" manoeuvring, including looping, rolling, the so-called Immelman turn and reverse turn. An extensive study of landing and taking off has also been made.

In his report on the tests, Pilot Carroll emphasized the importance of "taking off" and "landing," which are the dominating factors of the efficiency, and perhaps the longevity, of a pilot. Of the two, he says, landing is perhaps the more important, for it is in this phase that the majority of accidents and damages occur. A paper on "taking off" and "landing," by Major R. M. Hill, a British flying officer, is the only one known to have been published on these important manoeuvres, and it was this treatise that inspired the tests and developments undertaken by the National Advisory Committee for Aeronautics in this country.

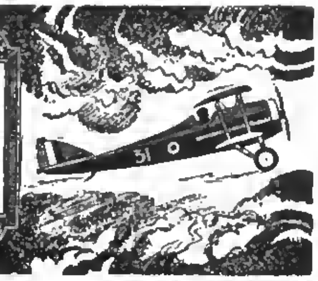
ELEMENTARY AERONAUTICS *and* MODEL NOTES



Scale Model Built by Aerial Age Reader

Douglas Young, of Westboro, Ontario, a veteran model builder and a member of the Flight Association of Ottawa, Canada, his completed a neat model of the Newport Chasse plane. This model is complete with all controls, bucket seat, turnbuckles, dummy rotary engine with cooling flanges, exhaust pipes, push rods, etc. The propeller, machine gun, etc., are all to scale and all details such as the instrument board, sprung chassis, etc., are carefully formed to correct proportions.

The finish is of aluminum color, with the red, white and blue insignias and rudder markings of the French Army Air Service.

The scale is one-tenth full size, the wing span being reduced in this proportion to approximately 32 inches.

Hydro Models Giving Good Performance

SGT. Joseph S. Ott, of College Station, Texas, whose extensive work on model aeroplanes has been mentioned in these columns before, gives an instructive description of one of his successful models, a 21-inch hydro which will fly 400 to 500 feet, rising from the surface of the water. This tractor model leaves the water after skimming the surface for only about 5 to 6 feet, is very dependable in its performance and never fails to take of properly.

The specifications of the Ott 2½-inch hydro model are as follows:

Wing span	21 inches
Wing chord	3½ inches
Weight	.97 ounce
Propeller diameter	7 inches
Propeller pitch	5 inches
Power—(elastic, 3-16 inch flat)	3 strands

The motor stick is 3-16 inch by 3-32 inch, with a ring located at the middle to support the rubber power in position. By this arrangement the propeller may be turned 800 revolutions without danger of twisting the frame too greatly.

A block of white pine ¼ inch by ½ inch is used for the propeller blank.

Floats are 1½ inches wide, ¾ inch deep and 4 inches long. The frame is built up of strips measuring 1-32 inch by a little less than 1-16 inch in section.

The wing has a pronounced dihedral which decreases the actual span to 21 inches, although the wing measures 24 inches in flat plan. There are seven bamboo ribs attached at each end to white pine spars 3-32 inch by slightly less than 3-16 inch.

Horizontal stabilizer measures 3½ inches in length and 4½ inches in width. Thread is used for the edges, completely around. A triangular jin aft of the stabilizer measures 2 inches in height and 3 inches in length.

Another of the Ott hydro models giving good performances is the little twin-pusher having a 26-inch wing span. Its weight is very low; a trifle less than 1¾ ounces. The specifications are as follows:

Wing span	26 inches
Wing chord	4 inches
Weight	1.74 ounces
Propeller diameter	7 inches
Propeller pitch	7 inches
Power—(elastic, 3-16 inch flat)	3 strands

The A frame is 26 inches long, ¼ inch by 1-16 inch in the center and tapering to 3-16 inch by 1-16 inch at the ends. Cross braces are 3-32 inch by 3-64 inch, using two X pieces and 3 straight members.

Hook and shafts for the propellers are of number 14 piano wire. There are two propellers, turning in opposite directions, to counteract against torque or twisting. The propeller blanks are cut from blanks of white pine ½ inch thick and ¾ inch wide.

Main wing frame is of pine. Diamond or pointed tips of bamboo. Seven ribs, 1-32 inch by 1-16 inch are used. Covering on the top surface only.

The elevator is 12 inches in span, 2½ inches wide. Bamboo construction throughout. No elevating blocks are used, but the elevator wing tips are bent upward about ½ inch to give the required lifting angle.

Chassis members are a trifle under 1-16 inch square.

There are two floats at the front and one at the rear of the frame. Front floats are 4 inches long, 1¾ inches wide and ¾ inch deep, coming to a point at front and rear. They are patterned after the shape of a snow shoe. Rear float 5 inches long, 2 inches wide and ¾ inch deep.

Two coats of Shellac are applied to the framework and wings to render them as completely waterproof as possible.

The elastic motor takes 950 turns and it is powerful enough to take the model off in a moment. By decreasing the angle of the front floats, the model will run over the surface for about 6 or 7 feet before taking off. Landings are made in perfect balance.

Best results are obtained when the main wing is located about ½ inch behind the center of gravity. This permits the model to assume a very flat glide when the power has been used up. Better gliding is also accomplished by a gradual decrease in the incidence or lifting angle of the elevator plane, altho if sufficient lift is not obtained, the model will not leave the water quickly and the duration of the flight will be decreased.

Flights of 800 feet are made with the 26-inch model, starting from the water under its own power.

Mr. Ott has designed quite a variety of models, from small tractors to compressed air types, and the details of some of the more popular types will be published in forthcoming issues of AERIAL AGE.

Hydro models designed by Sgt. J. S. Ott, U. S. Air Service. At the right is a 26" twin pusher. At the left a 21" tractor which will fly 500 feet

RADIO DIGEST

New York Mayor Requests Radio Appropriation

The special Radio Committee appointed by Mayor Hylan of New York City about a month ago decided to recommend the erection of a city broadcasting station on top of the Municipal Building.

The station is to cost $50,000, and its erection is to be under the supervision of the Department of Plant and Structures. The Board of Estimate will be asked by the committee to appropriate the sum at its meeting Friday.

The meeting was held in the office of Rodman Wanamaker, Special Deputy Police Commissioner, one of the members of the committee, with these other members in attendance: Borough President of Queens Connolly, Commissioner of Plant and Structures Whalen, Col. Barrett Smith of the Department of Water Supply, Arthur S. Tuttle, chief engineer of the Board of Estimate, and City Chamberlain Berolzheimer.

The appropriation covers not alone the broadcasting station, but many portable receiving stations that may be set up quickly in parks and other places where crowds gather—these receiving stations to have sufficient amplifying apparatus to carry to every ear in a multitude.

When the station is going, and the Mayor or one of the department heads wants to say something without using the medium of the public prints—presto! He calls for his radio crew, orders the receiving sets put up in all the boroughs, talks into the mouthpiece of his office telephone and the people will hear his own words in his own voice.

All the important orders and directions of the Fire, Health and Police Departments are to be broadcast from the Municipal Station. Whenever a distinguished visitor from abroad calls to pay his respects to the Mayor, the freedom of the broadcasting chamber is to be conferred upon him, so that the feted stranger may address not only a populace of newsboys in front of City Hall steps, but many thousands of citizens elsewhere.

Lest the appropriation be regarded as an extravagance, in view of the many broadcasting stations now keeping citizens listening close to home, this economy feature was mentioned, with suitable cheers, at the committee's meeting:

Music is to be supplied to parks through the municipal broadcasting station.

One band will do for all parks!

One really good band may be hired instead of several lesser bands.

The amplifying apparatus will do the trick.

Radio Tests at Camp Vail

Captain Clyde V. Finter, A. S., left for Camp Vail, April 10, 1922, under orders from the Chief of Air Service for the purpose of co-operating with that station in the development and testing of radio apparatus. This work will occupy about ten days. The plane which Captain Finter flew from Mitchel Field was equipped with the most modern type of radio sending apparatus. Mitchel Field was continuously in touch with Camp Vail by radio telephone during the period of these tests.

New Radio Station at Aberdeen, Md.

A new radio station has been opened at the Airship Field, Aberdeen Proving Grounds, with an S. C. R. 109 set as the main operating equipment. A wave length of 850 meters has been assigned this set by the Signal Officer of the 3rd Corps Area.

National Guard Unit Will Give Weekly Radio Concerts

The following statement has been issued by the Signal Corps of the National Guard of New York.

"The commanding officer of the 101st Signal Battalion, N. Y. N. G., realizing the tremendous interest aroused by the broadcasting of radio music and news, has authorized the institution of a series of radio concerts, to be held at the Signal Corps Amory, Park Avenue and Thirty-fourth Street, on Wednesday evening of every week.

"Such complete equipment as is necessary will be utilized to reproduce the best possible radio music. Tickets for these concerts may be secured by applying to Lieutenant W. B. Schreiber, of Company A, 101st Signal Battalion, Park Avenue and Thirty-fourth Street.

"Little is really known of the great work done by the battalion. Members of the organization, drawn from every walk of life, have been busy for months undergoing a course of instruction that includes, in addition to the popular radio telephony, radio telegraphy, Morse telegraphy and ordinary telephony. The organization is a federalized unit, the members drawing Federal pay for attendance at drill. The powerful station at the armory operates from Fort Wood, on Bedloes Island, headquarters of the 2d Corps Aera, which includes most of Greater New York.

"The training and education afforded the members of the unit provide new fields of endeavor for all. In addition to the technical work necessary and required of each man, the usual routine of military training is also included in the course of instruction. Marksmanship, elementary and advanced electricity, first aid, personal and camp hygiene and the ordinary infantry tactics compose the general program.

"The series of radio concerts is the best evidence of the thoroughness of the training afforded and provided by the organization. The operation of the receiving sets will be conducted by enlisted men of the battalion, many of whow knew little or nothing regarding the manipulation of the various pieces of apparatus at the time of joining the organization.

"Of course, there are numerous other features and advantages, as entertainments, athletics and any variation of club privileges make possible the enjoyment of membership in the organization that compares very favorably with the average social or athletic association.

"The history of the organization is a most interesting one and dates back to the late '70s, when the first signal company was organized in New York. The members have, as a unit and individually, taken part in the Spanish-American War and the recent great World War, establishing reputations that are looked upon with pride by the present organization. The enthusiasm shown around the armory by the members marks well the intense interest the men take in their work and the pride manifested in their being signalmen.

"Application for membership can be made to Lieutenant H. G. Martin, Jr., recruiting officer, 101st Signal Battalion, N. Y. N. G., Park Avenue and Thirty-fourth Street."

Presides By Radio

For the first time in history, two meetings of electrical men were called to order April 26 by radio telephone. Walter Newmuller, Secretary of the New York Edison Company, at the broadcasting station of the Western Electric Company, West Street, New York, talked before members of the New York Electrical League at the Hotel Astor and the New York Electrical Society at the new Hell Gate Station of the United Electric Light and Power Company.

He called the meetings to order at noon and after a short opening address introduced several opera stars, who rendered selections over the radio. Mr. Newmuller then went to the Astor to preside over the meeting of the New York Electrical League, and Thomas E. Murray, Vice President of the New York Edison Company, also rendered several selections over the radiophone. John Miles of the Western Electric Company discussed radio problems at the Astor.

International Conference To Standardize Radio

Paris.—The International radio conference of Americans, British, French and Germans, which is attempting world-wide standardization of wireless traffic, will resume its sessions at London on April 24, when it is hoped final agreements will be reached. The United States is represented by the Radio Corporation of America, England by the British Marconi Company, Germany by the Telefunken Company and France by Radio-France.

Five day sessions in Paris is understood to have been devoted principally to discussion of the use of different wave lengths by various countries to avoid interference and international agreements governing sending and receiving. These experts will meet in Berlin in June to present complete findings.

Although he declined to disclose the results of the conference, Edward J. Nally, president of the Radio Corporation of America, who, with Owen D. Young, vice-president of the General Electric Company, represents American interests, said the delegates were endeavoring to devise a means for the extension and proper control of broadcasting. He added that Germany, France and England were sending experts to the United States to study distribution methods there.

"One of our greatest hopes for the future," said Mr. Nally, "is the establishment of an international radio language or code, like Esperanto, which could be understood by all. This would place the activities of the whole world at everybody's ear. There is no reason why every American schoolhouse should not have a simple wireless apparatus to enable teacher and pupils to listen to what the rest of the world is doing."

Digitized by Google

Conference to Draw Schedule

The sudden increase in the number of radio broadcasting stations in and around New York city all operating upon a 360-meter wave, has produced a serious situation, which may develop into troublesome interference. This fact is realized by the operators of the stations in question, and there is a possibility that a conference will be held during the coming week to solve the problem caused by the stations.

In all probability some schedule will be evolved at the conference whereby all of the stations can operate during the day without interfering with each other. At the same time it is expected that the large commercial broadcasting stations which have been in operation for some time will be given a preference in operation.

New Radio Code Issued by Fire Underwriters

The National Board of Fire Underwriters have made public tentative regulations covering radio receiving installations that disclose considerable modification as compared with the requirements previously issued by fire underwriters.

The specifications that follow were drawn up by a special committee of the National Fire Protection Association, which is the authority for the national electrical code and whose findings are standards of engineering practice. Besides the underwriting organizations represented upon this special committee, engineers acting for the American Radio Relay League, American Telephone and Telegraph Company, Radio Corporation of America and and the Independent Telephone Association also participated.

The new rules are being published as proposed amendments to be included in future editions of the electrical code. It is stated that the requirements contained in the current edition of the code were based largely on the hazards incident to the equipment of wireless telegraph transmitting stations where antennae of considerable height and length were used and where the hazard of high potential equipment had to be considered.

The recent widespread installation of radio telephone receiving sets has necessitated a revision of the regulations. The receiving set having an indoor antenna is considered devoid of hazard. With any receiving set, the publication says the principal danger is from lightning brought in ovr the antenna to the equipment or to some part of the building. Where there is no exterior antenna this hazard is removed.

The following specifications are for receiving stations only:

NATIONAL ELECTRICAL CODE

Specifications (for Receiving Stations Only):

Antenna

"a. Antennae outside of buildings shall not cross over or under electric light or power wires of any circuit carrying current of more than six hundred volts, or railway trolley or feeder wires, or shall it be so located that a failure of either antenna or of the above mentioned electric light or power wires can result in a contact between the antenna and such electric light or power wires.

"Antennae shall be constructed and installed in a strong and durable manner and shall be so located as to prevent accidental contact with light and power wires by sagging or swinging.

"Splices and joints in the antenna span, unless made with approved clamps or splicing devices, shall be soldered.

"Antennae installed inside of the buildings are not covered by the above specifications.

Lead-In Wires

"b. Lead-in wires shall be of copper, approved copper-clad steel or other approved metal which will not corrode excessively, and in no case shall they be smaller than No. 14 B. & S. gage except that approved copper-clad steel, not less than No. 17 B. & S. gage may be used.

"Lead-in wires on the outside of buildings shall not come nearer than four (4) inches to electric light and power wires unless separated therefrom by a continuous and firmly fixed non-conductor that will maintain permanent separation. The non-conductor shall be in addition to any insulation on the wire.

"Lead-in wires shall enter building through a non-combustible, non-absorptive insulating bushing.

Protective Device

"c. Each lead-in wire shall be provided with an approved protective device, properly connected and located (inside or outside the building) as near as practicable to the point where the wire enters the building. The protector shall not be placed in the immediate vicinity of easily ignitable stuff or where exposed to inflammable gases or dust or flyings of combustible materials.

"The protective device shall be an approved lightning arrester, which will operate at a potential of 500 volts or less.

"The use of an antenna grounding switch is desirable, but does not obviate the necessity for the approved protective device, required in this section. The antenna grounding switch, if installed, shall in its closed position form a shunt around the protective device.

Protective Ground Wire

"d. The ground wire may be bare or insulated and shall be of copper or approved copper-clad steel. If of copper the ground wire shall be not smaller than No. 14 B. & S. gage, and if approved copper-clad steel it shall be not smaller than No. 17 B. & S. gage. The ground wire shall be run in as straight a line as possible to a good permanent ground. Preference shall be given to water piping. Gas piping shall not be used for grounding protective devices. Other permissible grounds are grounded steel frames of buildings or other grounded metallic work in the building and artificial grounds such as driven pipes, plates, cones, etc.

"The ground wire shall be protected against mechanical injury. An approved ground clamp shall be used wherever the ground wire is connected to pipes or piping.

Wires Inside Buildings

"e. Wires inside buildings shall be securely fastened in a workmanlike manner and shall not come nearer than two inches to any electric light or power wire unless separated therefrom by some continuous and firmly fixed non-conductor, making a permanent separation. This non-conductor shall be in addition to any regular insulation on the wire. Porcelain tubing or approved flexible tubing may be used for encasing wires to comply with this rule.

Receiving Equipment Ground Wire

"f. The ground conductor may be run inside or outside of building. When receiving equipment ground wire is run in full compliance with rules for protective ground wire, in 'Section D,' it may be used as the ground conductor for the protective device.

"Regulations covering sending stations have also been drawn up and copies may be secured from the National Board of Fire Underwriters."

Recruiting By Radio Brings Results

It will be remembered that the News Letter of February 18th published the fact that Mitchel Field had adopted a novel plan of recruiting by radio telephone and had sent broadcast a message calling for enlistments for the various Air Service organizations at that station. As evidence of the fact that this method is effective, letters have reached Mitchel Field from far and wide in reply to this request for recruits. The latest response came from Buffalo, N. Y., in which an applicant for enlistment stated he had received information by radio telephone that Mitchel Field desired recruits for the Air Service. By this and other means, and the very active recruiting efforts on the part of the recruiting office at Mitchel Field, 28 recruits were secured for the Air Service organizations at that station during the month of March.

Books on Wireless

RADIO FOR EVERYBODY. *By Austin C. Lescarboura.* Scientific American Publishing Company.

This volume has been written specially to meet the situation that has arisen as a result of the broadcasting system of radiophone concerts. It is written in language that the layman can understand, and covers practically every phase of the radiophone, from the apparatus at the broadcasting station down to the various types of receivers that are being used by the general public.

In his introduction Mr. Lescarboura says that in order to get into sympathy with the views of the novice he specially installed a receiver to listen into the concerts, so that he could study the subject from the viewpoint of music reception. "Indeed," he says, "the manuscript for this book was written on the very table where I have my radio receiving set."

The book is profusely illustrated with photographs showing various types of receiving and transmitting equipment used in wireless telephone work. There are also a large number of diagrams showing connections for different circuits.

One chapter is devoted to the tuning and adjustment of receiving sets, and another to "Making big sounds out of little ones, or the gentle art of amplifying."

ACQUIRING THE CODE. *By E. P. Gordon.* Wireless Press, Inc.

Now that broadcasting has become popular many novices listening in have been actuated by a desire to learn the continental telegraph code so that they can decipher the messages which they hear surging through the ether. This little volume goes into the subject thoroughly and shows the beginner just what to do in order to avoid many of the errors usually committed in learning the code.

Why Are ERICSON'S PRICES So Attractive?

Because they are absolutely the lowest, considering the quality of the material.

Extract from our price list:

OX5 Parts

8	Pistons with Rings	$20.00
16	Piston Rings	2.00
	Carburetor (Zenith)	15.00
8	Valves	7.00
16	Valves	12.00
	Connecting Rod, each	3.50
	Set of Connecting Rods (8)	20.00

Canuck, JN4 and Avro

Wing Panels, covered, each	$95.00
Landing Gear, complete	75.00
Propellers for OX5 (boxed)	15.00
Wheel with Tire and Tube, each	12.00

NOTE. Prices quoted at Buffalo. Duty Paid

ERICSON AIRCRAFT, LIMITED, 120 KING STREET, E, TORONTO, CANADA

What Is Your Problem In Commercial Aviation?

GETTING STARTED? All right, we have a stock of Airplanes and Motors ready to fly.
KEEPING GOING? We can help you because wa are the largest commercial aviation supply house in the country.
SERVICE? Johnson Service means good service, including a modern equipped flying field and shop.
INFORMATION? Our information department is at your service free of charge.
PRICES? Lowest prices consistent with best material.
GUARANTEE? Our customers must be satisfied always, or their money refunded.

Let us solve your problems in commercial aviation. Write us first and avoid costly delays. Our new catalog mailed on request.

A FEW SUGGESTIONS TO MAKE YOUR PLANE LOOK SNAPPY:

New Flottorp propeller, copper tipped......$30.00
New radiators, Curtiss or Standard 20.00
New upholstered wicker seats 5.00
New side cowl or cock-pit cowl Curtiss or Standard 15.00
New streamlined wheels, 26x4 .... 16.00
New Goodyear cord tires, 26x4 .... 10.00
New fuselage covers, ready to put on, Curtiss or Standard $15.00
New wind shields 2.50
New shock absorbers, per foot .... .05
New safety belts, American type 3.00
New center section with fittings, for Standard 10.00
New hose connections, all types .... .10
New hose clamps, all sizes ....$ .10
New Hartzell propeller, new design, brass tipped 60.00
New Warner tachometer with shaft 6.00
New thermometer, 15 ft. tube 7.50
New altimeters, 20,000 foot, luminous dial 10.00

Learn to Fly

Aviation is making such strides that it needs more men right now

You Can Learn To Fly

I can teach you how to become a successful pilot in a short time. My course is so arranged that you get only the things you need to make you a good aviator.

The Diggins Extension Course

is up-to-date, teaches you what you must know to become an expert flyer. This course is written by competent instructors right on my flying field. It is kept right up to the minute—all new developments in aviation are included. That is why it is recognized as the most complete and practical course offered today. My course saves you time and money because it prepares you at home so that you are ready to begin flying the day you arrive at the flying school.

Superior Points of the Diggins School

1. The Diggins school is the oldest, largest and most complete commercial aviation school in America.
2. The Diggins school is located in Chicago, the center of Aviation.
3. Living quarters and free employment service are maintained for students.
4. Diggins guarantees to make you a pilot.
5. Diggins' pilots get top notch salaries.
6. References, any aero club in America.

WRITE TODAY Write today for the new Diggins beautifully illustrated catalog.

ALL PLANES EXCEPT SINGLE SEATER AND JNS NEW

What is a DH-6? It is an English training plane built for OX-5 motor. Span 36 ft., chord 6 ft., surface 418 sq. ft. Lands 30-35 m.p.h. and climbs 2000 ft. in 5½ minutes, loaded. We remodel them making two cockpits instead of one long one, install a new gas system and use forward stagger instead of back stagger, giving the ship a much better performance and appearance. It has about twice the factor of safety of a Canuck, lands 10 to 15 mi. slower than a JN, is more stable and easier to fly than a Standard JI and will get in and out of even smaller places than an Avro. It has no equal for barnstorming, instruction or general passenger work. Plenty of spares—cheap.
Our ships and prices must be right. 37 of 4 different makes sold since Jan. 1st., 1922.
DEALERS—Let's get together. We will work with you.

Gentlemen:

We feel it is only fair to let you know of the wonderful success we have had with Lakeside Aviation Oil.

After making dynamometer and short flight tests at Keyport we decided to make a real flight test on Lakeside Aviation Oil, so we used it on part of the record-breaking flight of the Aeromarine Cruiser "Santa Maria" between Chicago and Key West via the Mississippi River.

This Cruiser encountered most unfavorable flying conditions on the lower Mississippi, where Lakeside showed itself far superior to any of the many oils we had used. The consumption of Lakeside Aviation Oil over a fifty-hour period was less than half of the best oil we had then found.

Needless to say, we were very much pleased and have used Lakeside Aviation Oil in all our extensive operations, with the same wonderful results. We have proven the truth of your slogan "COSTS LESS PER FLYING HOUR".

Thanking you for insisting that we try out your oil, we remain

Very truly yours,

AEROMARINE AIRWAYS, Inc.

TABLE OF CONTENTS

PUBLISHED WEEKLY BY THE AERIAL AGE CO., INC.
5942 Grand Central Terminal, New York City
Subscription: Domestic, $4; Foreign, $6
Entered as second-class matter March 25, 1915; at the Post Office at New York, under the act of March 3, 1879
Printed in U. S. A.

DELIVERING a 3-place Lincoln Standard Tourabout to Messrs. Bell and Long of Kansas City, Mo., December 21st, 1921, at zero temperature. (Note the aluminum covering on lower half of the radiator.) On account of the extreme weather conditions their flying instruction was transferred to the Oklahoma City flying field.

Service!

That is something you must be sure of when you purchase and operate an aeroplane. Curtiss offers a special Curtiss service such as you have a right to expect from the largest and most successful aeronautical organization in America. Curtiss service is prompt, efficient and reliable.

Curtiss Spare Parts prices for JN-4's, J-1 Standards and OX-5 motors are the lowest.

New JN-4 and J-1 Standard Parts

Item	Price
Fuselage complete	$340.00
R. or L. Wing Assembly, complete (with struts and wires)	292.00
New R. or L. Lower Wing, complete, less Fittings	90.00
Center Section complete, (with struts and wires)	49.40
Landing Gear Assembly, complete (with wheels and tires)	90.00
Tail Assembly, complete	116.40
New Propeller, Mahogany or Walnut (Copper tipped	$40.00
Propeller—Paragon—Used (Fine condition)	16.00 to 28.00
New Zenith O-6-D-S Carburetor (OX-5)	20.00
Tire Casing (unused 26" x 4")	4.80
Tire Tube (unused 26" x 4")	.60

The above prices are only a few samples; all spare parts priced accordingly. Write for parts price list for JN-4, OX-5, and J-1 Standard before you purchase spares. These reductions have been made in accordance with the Curtiss policy of helpful cooperation with American pilots.

Many flying organizations in all parts of the United States have joined our selling organization and are prepared to sell you Curtiss aeroplanes, motors and parts. Others interested in representing us under our new liberal sales policy may obtain details upon request.

USED CURTISS CANUCKS AND JENNIES AS LOW AS $650.00 READY TO FLY

Watch this space for list of America's best flying organizations—of course they use Curtiss Aeroplanes.

Aero Club Doing Good Work

THE following official bulletin from the Aero Club of America outlines far-reaching educational work which that organization is now engaged in. There is a certain group of individuals in the United States who are not going to let other countries get ahead of this nation in the "Air". They say that the world powers are today so financially embarrassed that they cannot support huge standing armies and navies and that the next emergency will be marked with a great offensive in the "Air", each side aiming to strike so sudden, so strong and so quickly, that the other will be unable to mobilize its civilian army and navy reserves.

But not only for national defense do they foresee the power of the aeroplane but realizing the all-importance of speedy transportation in any community or state, they foresee the building up of new industries relying on the speed of the aeroplane and demanding this new medium of intercommunication.

Although the aeroplane is a native son of the United States, it appears to be stunted in its growth in its own home locality. There is no directing thought in the country. Here and there one finds sporadic effort on the part of local clubs and societies to develop this power but they are all working at cross purposes. The time is now ripe for an association that all will join and with the united front all "Pull Together" for the furtherance of "Air Power" in the United States. The sponsors of this movement say that this body must be entirely independent and they are giving a great deal of thought and hard work to insuring a democratic, non-partisan, representative association that will not reflect the wishes of any particular community but speak in the behalf of the nation as a whole, so that the necessary legislation, the necessary airways, routes and landing fields, can within as short a time as possible be brought into existence, for they state that with these well established air routes, with the overhead taken care of as it should be, air lines will be a certain success and flying will become every-day and commonplace, safe and regular.

From a standpoint of national pride alone, prompted by no other motive than to keep America first in the "Air" at all times, they are working to bring this about and in this connection Rear-Admiral W. F. Fullam, U. S. Navy, retired, is making a tour of the United States giving lectures, showing the wonderful strides aeronautics has made and organizing the districts and states on behalf of the new association. His route is outlined as follows: Atlanta May 7th, Birmingham May 10th, New Orleans May 12th, Houston May 14th, San Antonio May 17th, Los Angeles May 20th, San Francisco May 24th, Portland, Ore., June 2nd, Seattle June 3rd, Spokane June 5th, Minneapolis June 9th and Chicago June 11th.

Admiral Fullam is attempting to have every city organize an Air Board, this Board to consist of representatives from each society or organization interested in aviation. Chicago has had an Air Board for some time now and it has proved an excellent organization for getting results.

Admiral Fullam attended the Sious City, Iowa, Convention last March and is in an excellent position to direct the other districts in their organization work.

Aerial Mail Night Flying

NIGHT flying, soon to begin on the air mail line across the continent, will render a double service to this country, in the opinion of aeronautical authorities.

Not only will it make it possible for a letter to be shot across the country from San Francisco to New York in twenty-four hours or so but the experience gained in operation will do much to speed the establishment of regular lines of aircraft which will fly day and night.

The competition between aeroplane and railroad train in carrying mail has been somewhat like the celebrated race between the hare and the tortoise, because the tortoise train travels all night while the hare plane stays still on the ground. Even without night flying air mail travels about twice as fast as train mail, but with night flying experts believe train mail will be made to appear like slow freight.

The announcement of night flying was made by Col. Paul Henderson, Second Assistant Postmaster General, in charge of air mail, with the reservation that it would not be attempted until the engineering staff of the service had completed its work of making this type of aviation safe.

When the first plane takes off from Curtiss Field, Garden City, for a night flight, it will not head westward with a depressed pilot, hand glued to stick and eye watching an unsteady compass, wondering where in this or the next world sunrise will find him.

Instead the plane will start with a confident aviator so equipped that it will be a difficult task for him to lose his way unless he loses both sight and hearing.

All the way across the continent this pilot and the pilots relieving him will be guided by beacons shining upward into the air from emergency landing fields thirty or forty miles apart. Thus, at no time during the flight will he be more than twenty miles from a field. In the event that he has to land because of motor trouble, a signal from the plane, a flare, will cause the illumination of the field by flood lights in addition to the beacon.

Each plane, instead of an oscillating compass which can not, because of drifting winds, be used with any certainty, will be equipped with a radio direction finder which will unerringly point the way to the next control field, despite fog, snow, rain or darkness.

These are the plans of the Post Office Department, and already they are well on the way to completion. The lights at the emergency fields, a great number of which already have been located, will be operated by the farmer owning the field.

THE NEWS OF THE WEEK

National Balloon Race

The National Balloon Race will be held this year from Milwaukee, Wisconsin, May 31st, 1922, under the auspices of the Aero Club of Wisconsin. The following prizes are offered: 1st prize, $1,000; 2nd prize, $800; 3rd prize, $600; 4th prize, $300; 5th prize, $200; 6th prize, $100.

Entries have been received from the following: Ralph H. Upson, holder of Spherical Balloon Pilot Certificate No. 48; H. E. Honeywell, Pilot Certificate No. 20; J. S. McKibben, Pilot Certificate No. 135; Roy F. Donaldson, Pilot Certificate No. 47; Warren Rasor, Pilot Certificate No. 50; John Berry, Pilot Certificate No. 24; Bernard Von Hoffman, Pilot Certificate No. 888; also three Army and two Navy balloons.

Santa Maria, With 12 Aboard, Finishes Flight From Cuba

Completing the last leg of a trip that started at Havana, Cuba, the giant flying boat Santa Maria arrived at its station in the North River, New York City, at 2:30 P. M., May 9th.

Aboard the craft were the crew of three and nine passengers. The flight was begun on the previous Wednesday, and was broken by seven landings. A distance of about fifteen hundred miles was covered by the boat, with an elapsed flying time of seventeen hours and thirty-five minutes, as compared with the fifty-seven hours required to make the trip by rail and steamer and the three and a half to four days required by steamer alone.

The Santa Maria was met by a committee representing the Army and Navy Air services, the Aeronautical Chamber of Commerce, aircraft manufacturers and the Aero Club of America. Among those present were Major A. N. Krogstad, representing General Bullard; Commander E. Frederick, representing Captain Vogelgesang, commandant of the 3rd Naval District, and Colonel L. La Tourette Driggs, chief of the New York National Guard Air Service.

The hydroaeroplane returned to the factory at Keyport, N. J., and will come back to the New York City Air Port to he exhibited, when its owner, the Aeromarine Airways, Inc., will inaugurate its summer flying season.

Field at Sheldon, Ill.

The Sheldon Airline, of Sheldon, Ill., announce that they have acquired a landing field eighty rods hy forty rods, clear on all sides, and marked with a "T." It is located on the main line hetween Indianapolis and Chicago, one mile south of Sheldon. Repairs and gasoline are availahle and fliers are welcome.

Commissioner Frazar in New York

Mr. E. W. Frazar, Commissioner, The World's Board of Aeronautical Commissioners Inc. for Japan and Corea, is in New York.

Speaking of Aeronautics in Japan, Mr. Frazer said Japan was far advanced and making wonderful progress on lines of aerial navigation. Mr. Frazar in co-operation with Mr. George Scott, Manager of the Rising Sun Oil Company of Japan (The Shell Oil Co.) has completed the delivery of oils and gasolene for the round-the-world flight from Shanghai via the Aleutian Islands to Alaska and San Francisco.

The stations supplied are Shanghai, Fuson, Tokyo, Kushiro, Etorofu Islam, Petropavlovsk, Kamchatka (Japanese territory), Attu Islands (American territory), Chicago Bay, Alaska points to San Francisco. Landing places in good harbors are about 150 miles apart.

The Tokyo Flying Staff located at Kasunigaura under command of Colonel De Master Semple, with Major Brackley (favorite pilot for the King of Belgium) Chief Instructor, is composed of thirty-six British Naval expert flyers. The entire staff are much interested in the around-the-world flight and will, with the assistance of Major Christie, U. S. Naval Attache, render all possible assistance to the flyers that the Pacific Ocean flight may be a success.

The Japanese fishing fleet between Yokohama and the mouth of the Kamchatka River, 1,945 miles, is composed of ten thousand fishermen. They with the Japanese and American Navy in Asiatic Waters, The Canadian Pacific Steamship Company, will be on the watch for them and render any assistance that may be required.

Mr. Frazer will be at Petropavlovsk near the mouth of the Kamchatka River during July and August and says those two months are best for the flight as the locality is free from fogs and ice.

Aerial Carnival Over Hudson

What was described as a new passenger-carrying seaplane record was established May 14, when the Aeromarine flying cruiser Menrosa, with twenty-seven passengers aboard flew from Keyport, N. J., to the New York airport, at Eighty-second Street and the Hudson. The Mendosa, an enclosed plane, luxuriously furnished, was a feature of a flying-boat carnival that attracted a throng of thousands.

The Mendosa flew from Keyport to the city, an air distance of thirty miles, in twenty-one minutes. The huge craft, painted white and flying an American emblem from one of its stay wires, circled over Riverside Drive and then gracefully alighted on the surface of the river. The cruiser "taxied" into shore, where an opportunity of inspecting it was accorded visitors.

Laurence La Tourette Driggs, founder of the American Flying Club, said the plane, seen here for the first time, was the last word in modern construction and equipment.

"It will not he long before the public will adopt this mode of transportation as a necessity," he said. "Why travel by railroad to Atlantic City, for example, a journeyof hours, when you can fly there just as comfortably in seventy-five minutes?"

The Mendosa has a spacious cahin with seats arranged along the side. It is electrically lighted and glass enclosed, a clear view thus being afforded of the country over which the traveler is passing. In the rear is a separate compartment seating three for those who desire seclusion. A feature is the arrangement of the pilot's seat whereby the passenger may watch the operation of the plane. The Mendosa has a wing spread of 104 feet and is motored with two 400 horsepower Liberty engines.

Contrasting in size with the Mendosa and the Santa Maria, a sister plane, was an Aeromarine sport boat, with a forty-eight foot wing spread, which was used in giving flights to those who preferred an open machine.

In addition to the flight program, a series of manoeuvres intended to demonstrate the various points of seaplane operation was carried out. The carnival was announced as opening the flying boat season in this city.

During the afternoon more than a hundred invited guests flew down the bay. While waiting their turns, they were entertained aboard the steam yacht Wadena. The Reception Committee consisted of Inglis M. Uppercu, C. F. Redden, H. F. Bruno, Earl D. Osborn and F. Rodriguez.

Among those present, most of whom took flights, were Commander Victor D. Herbster, representing the Naval Air Service; Major A. N. Krogstad of the Army Air Service; Lieut. Commander Marzos Zar of the Argentine Naval Commission; Murray Hulbert, President of the Board of Aldermen; Felipe Tahoada, Consul General of Cuba in this city; Mr. and Mrs. Laurence La Tourette Driggs, Miss Diane Gordon, Francis H. Markoe, Dock Commissioner John H. Delaney, and Mr. and Mrs. T. L. Oakley Rhinelander.

Police Air Reserve Is Now Part of Navy

The Aviation Division of the Police Reserves of New York City, including in its membership some of the best flyers in the war, has been mustered into the Navy Reserves. The actual transfer of the "flying cops" into Government service took place this week, and plans were said to be under way to furnish the naval reservists with complete aerial equipment.

Organized three years ago with Rodman Wanamaker, who financed the Wellman expedition, as one of the sponsors, the aerial division has been handicapped by lack of funds. Mr. Wanamaker was understood to have contributed heavily to the outlay as the aviators received no funds from the city. A training school has been maintained at the headquarters of the division in the old Greenwich Street station, where twenty students have been graduated as licensed pilots.

For a time the "flying cops" had the use of four hydroplanes lent by the navy. Five members owned aeroplanes which they placed at the disposal of the division. This completed the aircraft equipment of the force.

It was pointed out that the city still benefited despite the merging of the division with the navy as the aviators still retained their memberships in the Police Reserves, Class VI., into which the flyers have been allocated, renders them available in case of emergency.

Cleveland Aviation and Athletic Club

The inaugural banquet of the Cleveland Aviation and Athletic Club was held at the Hotel Winton on May 13. Addresses were delivered by Capt. Eddie Rickenbacker, Paul Henderson, Second Assistant Postmaster-General, Rear Admiral W. A. Moffat, Chief of the Bureau of Aeronautics, Lt.-Col. H. E. Hartney and Hon. William L. David. The banquet officially opened the club's new quarters.

The AIRCRAFT TRADE REVIEW

Aeromarine Performance

One of the most important developments in American civilian aviation is the successful operation of the Aeromarine Airways, Inc., of New York, Key West and Havana. Convinced that commercial aviation could be made a safe and financially successful business enterprise if conducted by an efficient organization possessing proper equipment, officials of Aeromarine Airways started their Key West Havana service in the winter of 1920-21. At the close of their second southern season on April 1st, last, Charles F. Redden, president, set to work checking up figures, operating costs and statistics. The books of the company showed that it had made money; but he wanted to know how closely the practical results coincided with the theories on which they have based their operations.

He found that Aeromarine Airways from November 12, 1920, to April 1st, 1922, had flown an aggregate distance of more than 150,000 miles and carried a total of 10,700 passengers—without an accident.

Since last November (1921) Aeromarine Airways made:

184 flights between Key West and Havana; 55 flights between Key West and Miami, Fla.; 91 flights between Miami and Bimini; 53 flights between Miami and Nassau; 16 flights between Miami and Palm Beach; 345 special charter and miscellaneous sightseeing flights.

In last period, the season just closed, 268,535 passenger miles were flown, in a total of 713 hours in the air. Out of the total of 749 flights, all but five were completed; the five being discontinued because of weather conditions, and the planes returned to the starting point. Not a single passenger or employee was injured in these operations. The schedule was maintained throughout, with the exception of the five postponed flights. Three types of flying boats were used: the 11-passenger flying cruisers of the F.5-L type, the Navy Coast Patrol 6-place Hs2L type, and Aeromarine 3-place flying boats.

"Efficiency of the operating personnel, pilots and mechanics and officials at each base, continuous inspection and maintenance of aircraft, adherence to the rule of 'Safety First' observance of weather conditions and knowledge of routes combined to bring about this progressive situation," says Mr. Redden in his report. "We know, now, that aircraft can be operated at a profit, without endangering lives."

International Air Lines in Europe

A meeting of the International Air Traffic Association recently held at The Hague was attended by the following persons: M. Hermant, representing the Compagnie France-Roumane; Mr. Jacobson, representing the Svenska Luft Trafik Aktiebolaget; Mr. Meisterlin, corresponding member of the Association for Norway and representative of Det Danske Luftfart Salskab; M. Pierrot, representing the Compagnie des Messageries Aeriennes; Lieut. Plesman, of the K. L. M.; Mr. Renaud, representing the Societe Nationale pour l'Etude des Transports Aeriens, and Herr Wronsky, representative of the Dantziger Luft Reederei and the Deutsche Luft Reederei.

Lieut. Plesman, manager of the Royal Dutch Air Navigation Company, was elected Chairman.

Discussion of plans for next summer resulted in the following international lines being decided on:

1. London-Amsterdam-Bremen-Hamburg Copenhagen.
2. London-Amsterdam-Bremen-Hamburg Berlin.
3. London-Brussels-Dortmun-Berlin.
4. London-Paris-Lyons-Geneva.
5. London-Paris-Lyons-Marseilles.
6. Amsterdam-Brussels-Geneva.
7. Paris-Strasbourg-Prague-Warsaw-Vienna - Budapest - Bucharest - Constantinople.
8. Konigsberg-Moscow, communicating with the railway services between Berlin and Konigsberg.

It was further decided that the Central Office should issue regulations for aerial services binding upon all the companies which were members. The Central Office was invited to communicate with the Secretariate of the International Postal Union, in order to call that Union's attention to the fact that, although it was impossible to maintain regular services thoughout the whole year, such services were possible from April to September, so that during that time the mail can be regularly carried by aeroplane. The Central Office was also invited to communicate with the Traffic Committee of the League of Nations. Efforts will be made in the direction of simplification of customhouse formalities.

It was further decided that motors should be equipped with an apparatus which served to muffle the sound; that large passenger aeroplanes should carry a pilot and assistant pilot; that machines destined for flights lasting over four hours should be equipped with a lavatory, and that the main parts of the machines should be constructed in such a manner as to be easily exchangeable.

The French Companies, the Belgian and the Slovak Companies have been invited to become members of the Central Office.

The next meeting will be held on July 31st, probably at Brussels.

Petrel Performance

An interesting test which demonstrates the advance in aeronautical engineering made since the armistice, was held in Kansas City, on the American Legion Flying Field, when a Petrel three seater was demonstrated in competition with a one hundred fifty horsepower rebuilt Standard J1.

The Standard is a plane belonging to Mr. John K. Legrone, a veteran pilot of nine years' flying experience. The Petrel used was the demonstrator of the Huff, Daland Aero Corporation which has a main sales base at Kansas City.

The two planes, equally loaded, were taken off the same line at the same time. The Petrel got off the ground in approximately 140 feet or about half the distance required for the Standard. Both planes climbed at their best angles. After the Petrel had reached an altitude of 800 feet it was about 100 feet higher than the other plane and about 400 feet in advance of it. Both planes then levelled off for a speed test, in which it was evident to all spectators on the ground that the Petrel was from twelve to fifteen miles per hour faster in horizontal flight than the Standard, powered with a 150 HP. Hispano.

This test was taken by four or five hundred spectators to be a definite proof of the fact that aeroplane design in 1922 is a very advanced matter over the elements of design in pre-armistice days. It shows that engineers have profited by the vast amount of wind tunnel experimentation made since the war; that American engineers can design planes around foreign aerofoil curves; and that a distinct advance must have been made when a plane of less than thirty feet of wing span can outclimb and outperform a plane of materially greater surface, lighter load per square foot, and much less power.

Asparagus by Air, Jersey to Boston

Fresh asparagus for the midday dinner in the Back Bay district of Boston will be cut the same morning in the Gloucester County, New Jersey, asparagus centre and shipped by aeroplane. Gloucester County is completing details of an air freight daily delivery of 1,000 pounds of the "grass" as they call it in Swedesboro, N. J., so there will be plenty to go around at other Boston dinner tables.

Radio messages to the station of the asparagus kingdom will expedite filling orders. Bert Acosta will have a radio in his Fokker and persons who have transmitters and find they are licking their chops as 1,000 pounds of fresh tender asparagus flies over their heads can call him by radiophone.

Asparagus must be caught young and the Gloucester County Board of Agriculture knows it. Its leading members met recently in Mickleton, at the home of S. Mason Carter, Chairman of the Board's Transportation Committee. Alexis L. Clark, chief of the State Bureau of Markets, attended. It was agreed to send Acosta in his Fokker on a test trip to Boston last week with his 1,000 pounds of "grass" and President White of the Gloucester County board as passenger.

Junior Aeronautical Engineer

The United States Civel Service Commission announces an open competitive examination for junior aeronautical engineer on June 21, 1922. A vacancy under the National Advisory Committee for Aeronautics, at $1,500 a year, will be filled from this examination. Applicants should apply for form 1312, stating the title of examination desired, to the Civil Service Commission, Washington, D. C.

AERIAL LAWS AND SURVEY OF SAFETY IN FLIGHT URGED BY AERONAUTICAL CHAMBER OF COMMERCE

THE following report covering the calendar year 1921 has been prepared by the Aeronautical Chamber of Commerce for the Department of Commerce.

Three deficiencies operate to the serious embarrassment of American aviation—meager capital, insufficient terminal facilities and popular doubt as to reliability. The correction of these deficiencies, and the consequent opportunity for the rapid growth of aerial transport, depend upon Federal regulation and reasonable control through an Aerial Code.

In a recent issue of Commerce Monthly, organ of the National Bank of Commerce of New York, it was declared: "Wise regulation may be expected to give a certain stability to the air transportation industry essential to any industry which must appeal for credit and for investment capital. Until this is attained air transportation can not be said to be on a business basis. From whatever point of view the subject is approached, the conclusion is inescapable that the enactment of an air law is the first essential step toward the development of commercial aviation in the United States."

The experiences of the inland waterways and the railroads in either burdening themselves with huge terminal debts, or in struggling selfishly for the exclusive control of available sites, a control which meant private monopoly and this, in turn, public burden, point the way for the sound economic treatment of the air port problem. The establishment of common terminals for the encouragement of all aviation, and for the national security in time of need, is a public responsibility, which, if neglected now, will invite difficulties within a few years similar to those in which the waterways and the railways now find themselves.

At the close of 1920, operating reports showed the existence of 128 terminals of all classes, of which five were in Canada, and three others devoted to airship experiment, leaving a net of 120 in the United States. Of this number, probably 20 could be classified as seaplane bases.

At the close of 1921, the operating reports showed a total of 146 air terminals, both land and water, within the United States. All were for heavier-than-air craft. This is an increase of 26 over the preceding year. Of the total number, 30 were classified as seaplane bases. Sixteen of the 146 were publicly owned or controlled.

Deprive the rail and ocean carriers of depots and docks, and operation must cease. Withhold terminals from the American aircraft industry, and aerial transport can achieve neither size nor reliability. The 146 terminals reported available to commercial aircraft in the United States represent the facilities for 600 machines without regard to geographical or business requirements. The wonder is that there has been so much paid fiying from so few fields.

In preparing the data for the Department of Commerce, the worst obstacle encountered in research and analysis was the lack of official machinery with which to obtain thorough and authentic information. Two courses were open—confidential data (as to identification) from the established companies making operating reports; and press stories, covering the general field. It is important to state at this point and to bear continually in mind that the press stories (with the exception of less than half a dozen fatalities) refer wholly to the gypsy flier and thus prove conclusively that the uncontrolled itinerant pilot encounters and causes most of the danger in flying.

One hundred and twenty-five established companies, operating 500 to 600 two and three-place machines, made 130,736 flights, covering 2,907,245 miles and carrying 122,512 passengers in the twelve months, October 1st, 1920-October 1st, 1921. In making their reports, these companies seemed careful to itemize all forced landings, crashes, etc. Yet the number of accidents in which persons were killed or injured, totals but 24.

Six Requisites for Safe Flying

Experience has taught that, in safe flying, there are the following requisites:

1. A machine aerodynamically and structurally sound.
2. An engine of sufficient power and which operates satisfactorily.
3. A competent, conservative pilot and navigator.
4. Air ports and emergency landing fields, sufficiently close together to insure gliding to safety.
5. Nation-wide weather forecasts specialized and adapted to the need of fliers.
6. Nation-wide chart of air routes.

Analysing the causes to which the 24 accidents are attributed: Of the six fatalities, three were due to stunting, two to gross carelessness on the field, and one to storm. Not a single person, passenger or pilot, lost his life in straight commercial flying. And with Federal regulation, controlling stunting and enforcing proper field policing and protection, it is believed certain most of these fatalities would have been avoided.

There were 21 persons injured in the 24 accidents. These mishaps were due to causes which could have been removed by Federal regulation or supervision—had landing fields, air routes and weather reports been fully available; had the field help been more disciplined; had the pilots been more alert through consciousness of licensed responsibility and had there been strict inspection of aircraft, engines, accessories and supplies.

These deficiencies, as compared with the requisites for safe flying, will be more carefully discussed later, when the case of the irresponsible itinerant is taken up, for it is he, rather than the established, incorporated company, that demands control.

122,512 Flew; Not One Killed

Yet, even conceding the foregoing, it is found that during twelve months, 500 to 600 commercial aircraft made 130,736 flights, traveling 2,907,245 miles, carrying 122,512 passengers (men, women and children) without a single fatality in flight.

Out of these 122,512 people, only 21 were injured in flying and in ground accidents, combined, or a ratio of:

0 fatality to 130,736 flights, and 2,907,245 miles flown, and
1 injury to 6,701 flights, and 138,440 miles flown.

The Case of the Gypsy Flier

It is estimated that during the calendar year 1921, 1,200 aircraft were engaged in civil flying in the United States and that these flew 6,500,000 miles and carried 250,000 persons. These figures are approximate and include both the itinerant and fixed base flying. Many press reports may be inaccurate as to causes, but they afford the only available index into the comparative safety of the total aerial activity.

A survey shows that 114 accidents occurred, not including those that involved Government-owned aircraft. Two of the 114 occurred in January, 1 in February, 2 in March, 6 in April, 16 in May, 13 in June, 13 in July, 28 in August, 16 in September, 8 in October, 8 in November, and 1 in December, progressing and diminishing as the flying season advanced and waned. The accidents were reported from all parts of the United States—30 being in the East, 43 in the Middle West (which has most of the machines and, generally speaking, the best natural landing fields) and 41 in the Far West.

What Caused the Accidents

The 114 accidents resulted in death to 49 persons and injury, more or less serious, to 89. In 48 instances there were no casualties. The 49 lives were lost in 33 accidents and injury to the 89 persons was caused in but 42 accidents.

Each of the 114 accidents recorded was caused by deficiency in one or more of the six necessary requisites for safe flying. Forty-nine were attributed to the pilot, perhaps through carelessness, perhaps incompetence, perhaps bad judgment combined with other factors. There is no doubt that a good pilot can guide a poor machine to safety with greater chance of success than a poor pilot can operate a first-class craft. Therefore, at the very top of the list of Governmental needs we place the Federal examination and licensing of pilots. During the war rather more than 17,000 young men were trained to fly. The knack of flying cannot be retained perpetually without practice, nor can it be maintained at a high degree of competency without regular examination on a common standard for all flying throughout the United States. The same is true of aerial navigators. Both pilot and navigator (many times they are identical) are of equal importance in safeguarding the lives of travelers by air.

Inadequate Landing Fields

Twenty accidents are attributed in whole or in part to inadequate landing fields or to the total lack of terminal facilities. Here is a duty directly imposed upon the Federal Government. During the war the Army and Navy acquired many terminals, most of which have since been abandoned. The fragmentary remainder has been slightly added to by the Air Mail, municipalities and private enterprise, but the United States is today woefully lacking in air ports for even the 1,200 craft in operation.

Lack of Weather Reports

While only 4 accidents are attributed to the lack of weather reports and 10 to the lack of clearly defined routes or limitations in traveling between or over cities, it is certain that aerial transport can not develop until these factors are met. As an illustration—two of the worst accidents in our flying history are attributed to these causes. As one was Naval and the other Military, they can not be included in the

Digitized by Google

civic survey, though in their results they were as harmful to civil flying prospects as though they had occurred to private individuals.

On March 2nd, a Naval seaplane, according to press reports, sideslipped on to a beach near Pensacola, Fla., and killed five bathers. Either the seaplane had no business over that beach or the bathers had no business on it. In either event, the fatalities would have been prevented had proper authority existed.

On May 28th a large Army plane crashed at Morgantown, Md., killing its seven occupants, who included some of the best-known figures in Military and civil aviation. According to the report of the Inspector General's investigators, the disaster was not due to defects in the machine or to incompetence on the part of the pilot, but to the terrific storm into which the ship flew and of which the pilot had not been warned. The investigators above referred to recommended that "steps should be taken to install a system for interchange of weather conditions and weather forecasts, between flying fields maintained by the various services, including Army, Navy, Mail Service and Coast Guard Service." It was further stated: "Obtaining information of weather conditions on a cross-country flight ranks in importance with the inspection of the engine and plane, and it is highly desirable that, in peace times, except in emergencies, no cross-country flights should be undertaken until available information of conditions on the way has been obtained."

Commercial cross-country or inter-city flights, it is evident, can not be encouraged with safety until there is full protection afforded by establishing civil weather reports and co-ordinating these with the various Government reports. This service, obviously, can not be provided by the several States.

Inspection an Imperative Need

Equal in importance with learning the qualifications of pilot and navigator is inspection of aircraft and engines. Out of the 114 accidents, 22 may be attributed to faults which proper inspection probably would have revealed—4 concerning the plane, 9 the engine and 9 an accessory, gas or oil. This inspection must be made at frequent intervals by Federal authority.

When it is remembered that operators of motor cars are required to qualify and that motor cars are periodically placed under rigid inspection, it is astonishing to learn that *anyone* can take *any* sort of flying machine into the air at the present time, with the consequent peril not only to himself and his passengers, but to many persons on the ground. If the standard of control were left to the various States, the hope of correcting this unfortunate condition would seem remote.

In one accident attributed to the attempt of the pilot to stunt an unsafe machine, two lives were lost. An investigator reported that the plane was not a factory-maintained product. He said: "It was one of the Army training types which had passed through many owners and which, my investigation shows, had been in at least four crashes previous to the final one. I found that the machine had been repaired by amateurs, that several of the spars and longerons were patched, some of them in four places. It was the giving way of these spars that undoubtedly caused the wings to collapse. The plane had lain out of doors in the open field all winter and one windstorm had blown it the full length of the field—about 1000 yards—and turned it over end. This spring it had been hauled back to its original position and put together again as best as might be. It was never inspected by a competent person, so far as I was able to learn. I found that the owner of the flying field—who is also a flier—had himself refused to fly this machine when the young man who took it up on its fatal trip was induced to become the pilot."

In the lack of any Governmental examination and inspection, the legitimate manufacturers and operators have endeavored to do what they could. They check up on their products, but their control is of necessity limited to localities and to a comparatively brief period of time. As flying increases, this method must become more hopeless and a stern responsibility is thus placed upon the Federal Government to provide an adequate system of examination and inspection.

Stunting Causes More Than 40% of Deaths and Injuries

Twenty-nine of the 114 accidents occurred during stunting. In these 29 accidents, 20 persons were killed and 36 injured—more than 40 per cent of the total. In other words, stunt flying in unrestricted areas was responsible for almost as many casualties as all other elements combined. Now stunt flying is necessary to testing and essential to warfare. It is believed advisable that all pilots know *how* to stunt so that, in case of an emergency, when *only* a stunt will save their craft, they will be able to act quickly, with understanding and without fear. But the habit of stunting for thrill is dangerous, fatal in many instances, and always harmful to civil flying. A Government system of control, limiting stunting to certain areas, will meet this unfortunate menace to aeronautics. In this connection, however, there is hope of general improvement. State Fairs and other amusements, since the war, have encouraged dare-devil flying as "concessions." But after stunts had killed many people and injured more under spectacular circumstances (such as collisions with grandstands, crashes on beaches, etc.) the New York State Fair Commission, according to press reports, eliminated the dare devil aerial acrobat from its list of attractions.

Collision in the Air

The danger of collision in the air is not great, providing levels of flight for aircraft under way are established and observed, and providing stunting is controlled. The 2 collisions reported occurred during stunt performances. In the first, one man was killed, and in the second, 2 were killed and one hurt.

Crowds Surge On to Field

Eight accidents causing injury to 7 persons are reported through carelessness on the field. In several notable instances the pilot, in order to avoid the crowd which surged out in front of his machine as he was taking off or landing, deliberately wrecked his craft. It is observed that at every flying demonstration, even at locally policed fields, the spectators ignore warnings and must be forced to keep back. This is illustrated by the long list of automobile race track casualties, where spectators get in the way. Only Federal rules rigidly enforced are able to meet this condition.

Searching for the "Unknown" Cause

Finally, 8 accidents which caused death to 4 and injury to one, are attributed to "unknown" causes. The hope of preventing accidents depends on learning—then correcting—the cause of each. It is evident that Federal authority is required to obtain information in such cases.

Flying Not Unsafe

From the foregoing it is seen that flying, even with the burden of unnecessary hazard imposed through the lack of an Aerial Code, is not unsafe.

Eliminating those deaths caused by stunt flying (20) and those attributed to lack of fields, weather reports and clearly defined air lines or routes (6) which only Federal authority can correct—23 fatalities remain—or one to about every 12,000 passengers, and one to 282,608 miles of travel,—unlicensed, unregulated and uncontrolled, and carried on for the most part in former war machines built from three to four years ago.

In case of the 125 operating companies, which flew 2,907,245 miles and carried 122,512 passengers on 130,736 flights, not a single fatality occurred in straight commercial activity. And it is from this record rather than from the itinerant picture that the public should judge the safety of travel by air. These companies approximate the condition in equipment and personnel which will be general when the Federal Government recognizes its duty and responsibility.

Furthermore, the aeroplane of 1921, powerful and beautiful as it appeared to us, and as it undoubtedly was in contrast with the gliders of Lilienthal and Chanute and even the Kitty Hawk biplane of the Wrights, will some day be to the ultimate flying machine what the primitive train of 1830 is to the Twentieth Century Limited. The designing and engineering features are progressing. Improvements in safety and efficiency are being constantly introduced. These, if aided by regulation and stimulation by the Government, assure security in the air travel of the near future comparable with that of the accepted means of transportation which we have today on rail, road and water.

Performance of B. M. W. 185-Horsepower Engine

This report by S. W. Sparrow deals with the results of a test made upon a B.M.W. engine in the altitude chamber of the Bureau of Standards, where controlled conditions of temperature and pressure can be made to simulate those of the desired attitude.

A remarkably low value of fuel consumption—0.41 pound per b.h.p. hour—is obtained at 1,200 r.p.m. at an air density of 0.064 pounds per cubic foot and a brake thermal efficiency of 33 per cent. and an indicated efficiency of 37 per cent. at the above speed and density. In spite of the fact that the carburetor adjustment does not permit the air-fuel ratio of maximum economy to be obtained at air densities lower than 0.064, the economy is superior to most engines tested thus far, even at a density (0.03) coresponding to an altitude of 25,000 feet.

The brake mean effective pressure even at full throttle is rather low. Since the weight of much of the engine is governed more by its piston displacement than by the power developed, a decreased mean effective pressure usually necessitates increased weight per horsepower. The altitude performance of this engine is, in general, excellent, and its low fuel consumption is the outstanding feature of merit.

RESEARCH PROBLEMS UNDER INVESTIGATION FOR THE SUB-COMMITTEE ON AERODYNAMICS OF THE NATIONAL ADVISORY COMMITTEE FOR AERONAUTICS

THE following memoranda prepared by the National Advisory Committee for Aeronautics outline the comprehensive character of research work now being done in the United States.

Langley Memorial Aeronautical Laboratory

Controllability Testing

This research is intended to provide definite data as to the response of an aeroplane to its control and to lead to the establishment of definite quantitative standards for controllability.

Tail Pressure Distribution

The distribution of pressure on the tail during steady motion, while interesting from an aerodynamic standpoint, tells but little about the loads and stresses arising, since these always reach their maximum value during accelerations. It is therefore desired to extend the work to the securing of a continuous record of the variation of pressure at a large number of points while maneuvering.

Wind Tunnel Tests on Wings

The necessity of this work is obvious, both to develop new sections of improved properties and to compare sections already tested under different conditions.

Similitude Testing (Wind Tunnel)

Tests are being undertaken in order to provide further data on the scale effect for wings of more modern type than the RAF-6, and also in order to determine the largest size of model that can be used in the Langley Field wind tunnel without interference.

Aileron and Rudder Tests

This work has been undertaken to find the relative efficiency of different locations for the aileron and rudder, and the relative effect of ailerons on different forms of wing.

Experiments with New Balances

The present type of N. P. L. balance, has certain serious disadvantages for high-speed work. Although comparatively satisfactory for low speeds, very large sizes in high speeds impose too great a load on the pivot and require too large a spindle to support the model. Experiments leading to the development of a new and improved type of balance should therefore be undertaken.

Tests for Slip-Stream Effect

The effect of slip-stream on the control surface and on the drag must be determined if wind tunnel testing is to be increased in usefulness. This is particularly necessary in connection with the loads on control surfaces.

Pressure Distribution for Thick Aerofoil Sections

The purpose of this research is to determine the variation of loading along the wing span for such wing sections and plan forms as are likely to be used in all-metal internally-braced designs. This research will supply data very much needed in design work.

Comparison of Wing Characteristics in Models and Free Flight

This research has been undertaken to furnish accurate and complete data on which to base performance estimates.

Determination of a Coefficient of Longitudinal Stability

In the course of free-flight research on stability, an attempt is to be made to determine the comparative values of various "coefficients" of longitudinal stability. It would be a great convenience to the designer to know that by a few simple tests there might be obtained a "coefficient" which actually expressed or indicated, longitudinal stability.

Preliminary Tests of Aerofoils in Free Air

The purpose of this investigation is to obtain large values of Reynolds number on tests of wings. This method not only gives the proper Reynolds number, but it also gives a velocity, a size, a degree of turbulence and an unrestricted body of air which is identical with that in which the full-sized aeroplanes fly. From a preliminary test it was estimated that the lift coefficient of any model can be determined to 2 per cent. and the drag to at least 5 per cent.

Small Oscillations in Steady Flight

This investigation has been undertaken to determine the magnitude of the angular oscillations about the three axes of the aeroplane when in steady flight, and also to determine the angular accelerations by differentiating the curves of the oscillations.

Pressure Distribution Over the Rudder and Fin

The purpose of this research is to determine the distribution of load over the rudder and fin both while the aeroplane is in steady flight and when it is being stunted.

Longitudinal Dynamic Stability

This work is a continuation of that already undertaken on static longitudinal stability. The characteristics of a number of different aeroplanes should be determined with a view to checking up the mathematical theory of their oscillations.

Pressure Distribution on Ailerons

Information on the pressures on the ailerons and on the wing surface surrounding them is desired by designers in computing the stress on the rear spar and also the stress on the aileron itself.

Pressure Distribution Over the Wings of an Aeroplane in Accelerated Flight

At the present time we have no data at all as to flow of air or the distribution of load over an aeroplane wing during accelerated flight, and it is quite probable that under such conditions the loading will be quite different from that in uniform flight. For this reason it is considered that careful study of the loading on the wings under conditions of stunting will be of the greatest value to aeroplane designers.

The Complete Study of an Aeroplane Oscillation

The purpose of this investigation is to aid in extending the theory of aeroplane stability.

The Effect of Longitudinal Moment of Inertia on Aeroplane Oscillations

It seems evident from theoretical work that the dynamic stability of an aeroplane will be greatly influenced by the ratio of the mass of the aeroplane to its longitudinal moment of inertia. The purpose of this investigation will be to determine the magnitude of this effect.

Standardization of Wind Tunnels

This investigation is to include the construction and test of a series of standard cylinders, wing sections, and airship forms, for comparison of the results obtained in different wind tunnels. The models are to be made in four different sizes.

Distribution of Loading Between Wings of Biplanes and Triplanes

This research is to be carried out at gap-chord ratios of 0.8, 0.9, 1.0, 1.1, and 1.2, and with various degrees of stagger for each aerofoil of a series, such as Albatross, RAF-15, USA-27, and USA TS-5 or Göttingen No. 255.

Free Air Tests of Spheres

As it seems fairly certain that the critical values in the resistance of a sphere are a measure of the turbulence in the air, measurements of the resistance of spheres in the free atmosphere are to be made to determine the degree of turbulence, and also to carry the Reynolds number higher than has been done before.

Bureau of Standards (Wind Tunnel)

The Direct Measurement of the Velocity of the Wind Stream in a Wind Tunnel, Independent of Pitot Tube Measurements

Wind speed measurements in wind tunnels at the present time are based entirely upon Pitot tube determinations of wind speed, which in turn are based (1) upon the theoretical head developed in a Pitot tube, or (2) upon calibration of the Pitot tube on a whirling arm which involves corrections for swirl. Other independent measurements of wind speed are desirable.

The Measurement of the Steadiness of the Wind Stream and the Effect of Unsteadiness on the Air Resistance of Models

The purpose of this investigation is to develop methods for measuring quantitatively the unsteadiness in the flow of wind streams, including (1) unsteadiness in distribution, and (2) unsteadiness in time.

Digitized by Google

The Effect of Turbulence of the Wind Stream on the Resistance of Bodies of Various Shapes and Its Bearing on Scale Corrections

This investigation is undertaken to determine the effect of turbulence in wind streams on the resistance of models.

Bureau of Standards (Aeronautical Instruments Section)

The Investigation of the Elastic Properties of Springs for Aneroid Instruments

The purpose of this investigation is to determine the performance characteristics of the Bourbon tubes used in aircraft instruments.

The Investigation of the Elastic Properties and Hysteresis of Diaphragms

The purpose of this investigation is to determine the characteristics of various types of diaphragms used in aircraft instruments for measuring pressures with a view to facilitating the rational selection and design of diaphragm elements for any specified purpose. The investigation is to include flat and corrugated metal diaphragms, slack diaphragms, and sylphon diaphragms.

The Investigation of the Behavior of Air-Speed Instruments in an Air Stream Under Reduced Pressures

The purpose of this investigation is to determine the performance of air-speed instruments under reduced pressures and at low speeds in order to make possible the more accurate determination of the air speed of aircraft.

Leland Stamford

Air Propeller Research

In this investigation a large number of models previously used in the tests reported on in Reports Nos. 14, 30, and 64, of the National Advisory Committee for Aeronautics are to be examined by means of the aerofoil theory of the propeller, and the results compared with the results of wind tunnel tests on these sections.

SHOWING AN AVIATOR HOW HE FLIES

AFTER nearly twenty years of flying without knowing just how he did it, man has now conceived a means of recording what an aeroplane pilot does and how the aeroplane responds. Aeroplane designers, builders, owners, instructors and pilots are delighted, though surprised, over the revelations of a method of recording accurately what an aviator does in executing any maneuver in an aeroplane, and also for securing exact data on the performance of an aeroplane in flight. This method has just been devised by the aeronautical experts and pilots of the National Advisory Committee for Aeronautics.

Three special instruments have been perfected to record the speed of the aeroplane in the air, the loadings or changes in weight on the wings, and the movement of the controls by the pilot.

Although fairly complicated themselves, the operation of these instruments is simple and mechanical, the recording being done by means of a photographic film. The results reveal for the first time a practical method of securing information in testing new types of aeroplanes, and for determining the ability and technique of a pilot. The last function of the instruments will be of great value to the pilots themselves and to instructors of novices, who are seldom able to recall just what they did with the controls at a certain point of a flight.

Three Instruments Record All Moves

The first instrument is an air speed meter, a device for recording the speed of the aeroplane through the air. A second is used for recording variations in the loading on the wings in flight, and the landing carriage when landing, taking off, or while running along the ground. In flying through a loop, for example, the pilot is sitting down hard as he goes up and again as he flattens out, but he is literally hanging in his belt at the top of the loop. It is these variations in load on the wings, due to the weight of the aeroplane and the aviator in the air that are recorded by this instrument and the weight on the carriage while on the ground. The third device, the control-position recorder, indicates the exact position of all the controls during any maneuver, or part of a flight. When the pilot gives his ship left rudder it is recorded in degrees, when he dives by pushing on his "stick," or pulls it back to lift the nose, these movements are shown on the record of the flight. After he lands, there is no argument as to what he did, for it is plotted from an automatic record. If one pilot reported that a certain aeroplane was not controlable, he could be checked up by having another pilot put the aeroplane through the same maneuvers, and then comparing the records of both pilots as delineated by this new instrument.

Instruments Act In Unison

These three instruments are synchronized to operate simultaneously, by means of a timing device which makes possible the coordination of the three records into a composite one available for study and analysis. The instruments themselves are not bulky and they do not interfere with the movements of the pilot or operation of the aeroplane. All the attention they require is the throwing of a switch, before a maneuver is begun and when it is completed, to see them all in operation and to stop them.

When the flight is completed the photographic records with their delineations of the pilot's movements and the aeroplane's performance are taken to a laboratory, greatly enlarged for study, and then plotted on a single sheet so that a complete story of the particular flight or maneuver is ready for analysis.

The instruments developed have been employed at the Committee's free-flight laboratory at Hampton, Va., by Test Pilot Thomas Carroll, in studying ordinary and stunting maneuvers, including looping, rolling, the so-called Immelman turn and reverse turn. An extensive study of landing and taking off also has been made.

In his report on the tests, Pilot Carroll points out the importance of taking off and landing, which are the determining factors of the efficiency, and perhaps longevity, of a pilot. Of the two, he says, landing is perhaps the most important, for it is in this phase that the majority of accidents and damages occur. A paper on taking-off and landing by Major R. M. Hill, a British flying officer, is the only one known to have been published on these important maneuvers, and it was this treatise which inspired the tests and developments undertaken by the National Advisory Committee for Aeronautics in this country.

Keeping Tabs on the Pilot

Application of this research work are seen in designing new aeroplanes based upon performance tests, testing advanced and hitherto untried types, and for study by instructors and pilots themselves. The author states: "It reveals to even the skilled pilot startling facts as to his technique." "It is surprising to the flier," he says, "to see an accurate record of his every movement of the controls in the air and the fluctuation of the loading and air speed which have given him but fleeting impressions while he was in the air." Up to the time of these developments in recording instruments, designers and engineers had to depend upon the memories of the test pilots as to the performance of a particular aeroplane. The pilots' recollections were often vague and they frequently disagreed as to the same aeroplane, due perhaps to the personal equation. Today, however, a review of the finished chart by the flier enables him to recall his actions, the response of the aeroplane, and give a comprehensive report, which frequently adds much to the delineations on the chart.

Hitting a Four and One-Half Ton Blow

In one of his recent tests, Pilot Carroll made an especially bad, or "pancake" landing, by levelling-off about six feet above the field, instead of a foot or so as is usually done, to see what effect on the aeroplane a loss of flying speed at that height would have. The record of the blow in vertical acceleration showed that he hit the ground with a force of 4½ times the weight of the aeroplane, or a total force of about four-and-a-half tons. Strangely enough there were no dire results, except that one of the rubber shock absorbers broke. In careful and regular landings this force seldom exceeds 1½ to 2 times the weight of the aeroplane.

Further developments in perfecting these recording instruments include the addition of a recording device to show the progressive speed or revolutions of the engine, and another device to record the actual force or power the pilot applies to his controls, that is, how many foot pounds he exerts in pulling his stick back or pushing it forward in a particular movement. This, it is said, will indicate whether or not the pilot "drives" with a loose or tight rein, and whether he abuses his controls and the aeroplane itself.

ADVANTAGES OF AERIAL MAIL

Extracts from Address by C. G. Peterson, of the Wright Aeronautical Corporation, Paterson, New Jersey, at a Luncheon of the Engineer's Club and the Flying Club of Baltimore

AS I see the situation, the most helpful sign of the present time for commercial aviation is the attitude of Congress in realizing the necessity of having private contractors carry mail by air. There have been two bills presented on this subject, one by the Honorable Halvor Steenerson, Chairman of the Committee on Post Offices and Post Roads, and one by Honorable M. Clyde Kelly, of Pennsylvania, a member of that committee. Let me quote from a prepared statement given by Mr. Kelly in May: "It has never been the policy of Congress or the Post Office Department to monopolize the carrying of mail matter by aircraft. It is believed that more rapid advancement can be made and more economical service given if private concerns are encouraged to perform this task of transportation." In looking at what can be accomplished by aerial transportation of mail, let us take a concrete example of a proposed air mail route between two cities—New York and Chicago. I will give you some actual figures on the quantity of mail now moving between those cities, the time which can be saved, and the costs of transporting this mail by aeroplane.

There are approximately 25 tons of firstclass mail daily from New York to Chicago. This includes the gateway mail at each end and considerable other mail matter, in addition to letters. There are on an average of 160,000 letters a day collected in New York City for delivery in Chicago City. This quantity does not include gateway mail at either end. The quantity of gateway mail is several times this amount. There are approximately 325,000 letters a day sent from Chicago to New York for delivery in New York City. The figures given are for letters and firstclass mail, and do not include other classes of mail of which there is a tremendous volume.

I will show you in detail from charts prepared from the present actual train schedules the time and quantity flow of this mail between New York and Chicago. These charts also include the lay-over time between the arrival of the train and the delivery. On these charts we have shown a mail plane "flight" paralleling each of the principal mail trains. It must be noted in this connection that the time of arrival and departure of most of these trains has not been set for the convenience of the Post Office Department, whereas if mail planes are operated their time of departure can be scheduled to meet the postal requirements.

WESTBOUND

Train No. 43, the newspaper train, with three 60 foot R. P. O. cars and 5 storage cars, leaves New York at 2:10 A. M., arrives in Chicago 24 hours afterward, and its mail is delivered in Chicago at 9 A. M. of the second day, over 31 hours after it leaves New York.

Flight No. 1 will leave New York at 2 A. M., arriving in Chicago at noon for delivery downtown by 2 P. M., saving one business day on 42,000 letters.

Train No. 19 with one 60 foot R. P. O. car and one storage car leaves New York at 5:31 P. M., arriving in Chicago the next afternoon at 4 P. M., too late for delivery that afternoon, and the mail is delivered in Chicago 9 o'clock the following morning 40½ hours after it leaves New York.

Flight No. 3 will take the mail from train No. 19 at Erie, flying it to Chicago, to arrive at noon for distribution by 2 o'clock that afternoon, saving one business day on 42,000 letters.

Train No. 35, is a very heavy letter train, leaving New York at 8:40 P. M., with one 60 feet R. P. O. car and 5½ storage cars, arriving in Chicago at 8 o'clock the next morning. Its mail lays over until the next morning and is delivered 35 hours after leaving New York.

Flight No. 5 will leave New York at 8 P. M., arriving in Chicago at 6 A. M., for the first delivery in the morning, advancing 42,000 letters one business day.

Flight No. 7 is an additional plane leaving New York at the same time but carrying mail for West of Chicago. Flight No. 7 arrives in Chicago at 6 A. M. By using additional planes out of Chicago connecting with Flight No. 7, the mail can be flown to arrive in St. Louis at 10 A. M., to be delivered by noon—to arrive in St. Paul at 11 A. M., to be delivered by 2 P. M.—and to arrive as far West as Kansas City by noon, to be delivered by 2 P. M., saving one business day on 42,000 letters.

Train No. 93 leaves New York at 9:26 A. M., carrying one 60 foot R. P. O. car as far as Cleveland where it arrives at 4:35 the next morning for delivery approximately 24 hours after it leaves for New York.

Flight No. 9 leaves New York at 6 A. M., arriving in Cleveland at noon for delivery by 2 P. M., saving one business day on 42,000 letters.

EASTBOUND

Train No. 32 with one R. P. O. car and four storage cars leaves Chicago at 1:50 A. M., arriving in New York 26 hours later, and its mail is delivered at 9 A. M. of the second day, over 30 hours after it leaves Chicago.

Flight No. 2 will fly from Chicago at 3 A. M., arriving in New York at noon with 42,000 letters to be delivered downtown by 2 P. M., saving one business day on 42,000 letters.

Train No. 22 with one R. P. O. car leaves Chicago at 5:30 P. M., arriving in New York at 5:25 P. M., too late for delivery and its mail is delivered 9 A. M. of the second day, over 38 hours after it leaves Chicago.

Flight No. 4 will fly from Erie at 6 A. M., with the New York mail taken from Train No. 22 which passes through Erie at 5:15, and Flight No. 2 will arrive at New York at 10 A. M. to be delivered downtown by noon, saving one business day on 42,000 letters.

Flight No. 6 will fly from Chicago at 12 o'clock midnight with the mail for Buffalo, Rochester, Syracuse, which has missed train No. 22 at 5:30 P. M. Flight No. 6 will arrive at Erie at 4:30 A. M., transferring its mail to train No. 22 which arrives in Syracuse at 10:45 A. M. for delivery at noon, saving one business day on 42,000 letters.

Train No. 28 with three R. P. O. cars carrying the heavy letter mail leaves Chicago at 11:15 P. M., arriving in New York at 7:15 A. M. of the second day, distributing its mail over 32 hours after it leaves Chicago

Flight No. 8 flies from Chicago at 11 P. M., arriving in New York at 8 A. M. the next morning for distribution 10 hours after leaving Chicago, saving one business day on 42,000 letters.

Flight N. 10 is to forward mail flown from cities west of Chicago. This mail could be flown by air leaving Kansas City at 6:30 P. M., leaving St. Paul-Minneapolis at 7:00 P. M., leaving St. Louis at 8 P. M., leaving Chicago at 11:00 P. M., arriving in New York at 8 A. M., the next morning with 42,000 letters advanced one business day.

Three routes are being investigated by our corporation for a flight from New York to Chicago. We are making an analysis of the weather conditions, the possibility of selecting good emergency landing fields, and the probability of density of traffic along these three alternative routes.

The first route is along the Southern boundary of New York State through Binghamton, Elmira, Erie and Cleveland, to Chicago. The second route is the present mail route through Bellefonte to Cleveland and Chicago. The third alternative route is somewhat longer but present data indicates that the all year around weather conditions will be considerably better. This route is known as the Southern Pennsylvania route through Reading, Harrisburg, Pittsburgh, Columbus, Dayton, and Indianapolis to Chicago. If this Southern Pennsylvania route is selected as a trunk airway for a New York-Chicago flight, the logical point of connection from Baltimore and Washington would be at Harrisburg, which has been selected as the probable location for a radio control station. It will probably be about an hour's flight from Baltimore and Washington to Harrisburg, so the westbound mail from Baltimore and Washington could be dispatched later than the time of the flights leaving New York. On Eastbound mail, the mail for Baltimore and Washington could be flown from Harrisburg and arrive in Baltimore and Washington before the arrival of the through flights in New York.

These charts and the figures given show the actual time which can be saved by flying the mail, and give an idea of the quantity now being dispatched. The cost is the next important item, and in general since we have compiled these detailed figures we have been surprised at the moderate cost of such a service. We have based these costs on the contractor being able to make a four years contract with the Post Office Department. We have figured on the contractor establishing the aids to navigation required. We have figured on the contractor leasing an emergency landing field at every 18 or 20 miles along the route. At each landing field there will be a powerful Beacon light, an illuminated sign, flood lights for landing, and an illuminated indicator giving the direction and velocity of the wind. At approximately every 150 miles we have figured on the contractor establishing a radio compass station. Each plane will be equipped with a combined radio telephone and telegraph set. An automatic sender on the

Digitized by Google

plane will telegraph at short intervals the plane identification number. The two radio compass stations between which the plane is flying will chart the position of the plane from these intermittent signals. If the pilot should get off the course he will send an automatic message to the nearest radio compass station. The compass station will telephone to him the compass course to follow and the distance to get back on the course. By this method the pilot will not need to receive telegraphic messages, as the instructions will be sent to him by telephone. Furthermore, he will not need to use his telephone except when he desires. This leaves his attention undivided for maneuvering his plane except when he desires information. We have figures on divisional points with shops and hangars approximately every 250 miles. At these divisional points the mail will be transferred to a fresh plane, fully serviced, and a fresh pilot.

Inasmuch as a trunk air line from New York to Chicago, equipped for day and night flying, will spell the success or postponement of commercial aviation in this country, we consider it advisable for the radio compass stations and the divisional points to be under the control of the contractor so there may be no division of responsibility. We have figured on the contractor using new modern planes which will carry at least 1,000 pounds of mail, with a cruising speed of 100 miles per hour, and a high speed of 20 or 25 miles faster. We estimate that the cost of operating this service, based on a four years contract, flying four planes Eastbound and four planes Westbound daily will be approximately $1,863,000 per year. The four Eastbound planes will expedite 210,000 letters a day, and the fohr Westbound planes another 210,000 letters a day, or saving a business day on 420,000 letters a day. Flying on 310 business days a year would mean 130,000,000 letters per year, and the cost would be less than 1½ cents per letter. This works out that the total cost per mile flown is about $1.00, which is at the rate of one mill per mile per pound.

Now the figures that I have given above indicate what can be reasonably expected in the future. But it must be remembered that in organizing as long a line as this, it will be inexpedient for either the contractor or the Post Office Department to undertake a contract of such magnitude as four planes each way daily. We have therefore prepared alternative figures on flying one plane each day each way. In making up this estimate we have left in all the costs of all the aids to navigation given in the larger estimate, including emergency landing fields, Beacon lights, and radio compass stations, so that the costs given will cover day and night flying. We estimate that flying one plane each way each day between New York and Chicago will cost approximately $800,000 a year based on a four year contract Based on a 1,000 pound load, the $800,000 yearly cost, plus 5%, gives a rate of 1¼ mills per mile per pound or 4¼ cents per mile per cubic foot of cockpit mail space in a plane. On this basis of one round trip per day approximately 25,000,000 letters would be expedited yearly from New York right through to Chicago, and the cost per letter, $800,000 divided by 25,000,000 letters, would be a little over 3 cents per letter, that is if all the mail is *through* mail. If the flight is arranged so that *way* mail can be carried either between intermediate cities or advancing part of the mail from trains which had already carried it some of the distance, approximately 50,000,000 letters per year could be expedited, and the cost would be only about 1 6/10 cents per letter.

Let me quote again from Congressman Kelly, who says: "While the payment for the transportation by aircraft would practically equal the revenues, that fact should not be conclusive argument against the plan, when it is realized that the rural mail carrier receives two cents for every letter, paper or parcel delivered, more than the entire revenue received by the Post Office Department. It is believed a worthy project to continue the rural mail delivery for the promotion of the common welfare."

Another point to be considered is that both bills introduced by Chairman Steenerson and Congressman Kelly call for an increased rate of postage when the sender desires to make use of the air mail. Both bills, however, would allow the Postmaster General to send other mail in order to make up the full capacity of the plane. The use of this additional postage could be expected to grow rapidly and thus cut down the net cost to the Government. It must also be remembered that in preparing the costs of aerial mail, we have not deducted the present cost of transportation by rail. These detailed figures show that the cost of yearly operation is not excessive for the saving of a business day on millions of letters.

Both of the bills now before Congress give a maximum rate per pound per mile above which the Postmaster General will not be allowed to contract for. Unfortunately, the rates given in both bills are too low. Mr. Kelly says of his bill: "This measure has been approved by the Postmaster General with the provision that the rate should be changed to 2 mills per pound per mile." We are heartily in accord with the desirability of either of these bills being passed with a rate of 2 mills per mile per pound, or its equivalent space rate of 5 cents per mile per cubic foot of mail compartment in the plane. The Post Office Department can be depended upon to make their bargains with contractors at or below these rates to protect the interests of the people.

It is urged in view of the promotion of the common welfare which can be accomplished by saving a business day on business letters from the Eastern seaboard to the middle West, and a corresponding saving on letters to the extreme West, that the Engineer's Club and the Flying Club of Baltimore both officially make known to the Post Office Committee of the House and their representatives in the House and in the Senate, their desire as citizens of Baltimore for the passage of the bill to allow the mail to be flown and at rates of remuneration for the contractor which will allow him to establish a safe, efficient, and dependable service.

Baltimore Flying Meet

THE Aeronautical Chamber of Commerce is co-operating with the Flying Club of Baltimore in arranging a flying meet to be held in Baltimore on May 30th. The program embraces some interesting events calling for participation by commercial machines.

Approximately $1,300 to $1,500 in prizes are being arranged. The meet has the support of the local Baltimore civic organizations and particularly of the National Guard. The following is the tentative program:

1. Efficiency Contest
Conditions

1. Having useful load (including fuel) of more than 750 lbs.
2. Contest decided on formula — $E = S\frac{(w-t)}{g}$

   S—speed over course in m.p.h.
   w—total weight loaded.
   t—tare, weight of machine empty plus oil and water.
   g—fuel consumption in gallons over course.
3. Course, Logan Field, to Filtration Plant, to Bay Shore Park, to Logan Field, one circuit 15.4 miles. Entrants will make 4 circuits. Time to be taken from initial to final crossing of Logan Field. Machines off at 1 minute intervals.
4. Prizes: First, $500. Second, $200. Third, $100.

2. Race for Military Planes
Conditions

1. Handicaps.
   D. H., time over course X 1:00, official time.
   S. E., time over course X .92, official time.
   Fokker D. VII, time over course X .92, official time.
   Vought 180 H.P., time over course, X 1:00, official time.
2. Course—Same as (1)—2 laps. Time, taken from initial crossing of Logan Field. Machine sent off—1 minute interval.

3. Precision Flying National Guard Pilots
Conditions

1. Pilots shall climb to 3,000 ft., throttle motor and spiral down, landing at circle. Pilots will be allowed to "jazz" motors in very short bursts, three times for purpose of clearing motor. Pilots should endeavor to make maximum number of spirals and pull up at a minimum distance from center of circle.
2. Formula for determining winner: $\frac{E-N}{D}$

   N—number of spirals made. D—distance in feet from mark.
3. Pilot will, after landing, wait for judge to mark position of center of circle on ground, and will then taxi in to line, clearing way for landing ships. Judge will immediately measure distance from mark.

4. Sport Plane Efficiency Contest
Conditions

1. Pilots will take off and indulge in any acrobatics such as loops, rolls, spins not under 500 ft., examples of slow flying and slow landings, which the pilot decides will show the value of his ship.
2. Efficiency of performance to be determined by 3 judges.
3. Any pilot stunting under 500 ft. or over crowd will be disqualified for any further participation in meet.
4. Prizes: First, $250. Second, $150. Third, $100.

5. Bombing of Fort Carroll by U. S. Air Service Pilots
Conditions

1. Pilots will bomb a silhouette of Fort Carroll with smoke bombs from altitude of 3,000 feet, using 25 lb. smoke or including bombs.
2. Details to be decided by U. S. Air Service and Aeronautical Chamber of Commerce.

6. Balloon Sniping Contest, National Guard Officers
Conditions

1. Pilot and observer, latter with pump gun loaded with small shot will climb to 2,000 feet, when at this altitude, three balloons of approximately 2 feet diameter will be released at 1 minute interval. The observer who shoots down these balloons in shorter time, wins.

7. General Flying and Demonstration of Commercial Planes

Commercial planes are allowed to carry passengers and give any demonstrations they desire. Commercial planes who desire to carry passengers for pay during meet may do so, except during events Nos. 3 and 5.

LANDING FIELDS IN THE UNITED STATES

Long Island

Gravesend Bay.—Latitude 40° 34' N., longitude 74° 00' W.
Fair grounds; near Coney Island; mile track; ideal.
New Dorp.—Latitude 40° 34' N., longitude 74° 06' W.
No data.
Plum Island.—Latitude 41° 10' N., longitude 72° 12' W.
Fort Terry Parade Ground; across Long Island Sound.
Sayville.—Latitude 40° 45' N., longitude 73° 05' W.
Emergency field; Sayville radio towers near.
Sotuhampton.—Latitude 40° 54' N., longitude 72° 25' W.
Emergency; near beach, also at West Hampton.
Westbury.—Latitude 40° 45' N., longitude 73° 35' W.
Roosevelt Field; the best on Long Island; 3,000 feet square; four hangars.
Woodbury.—Latitude 40° 50' N., longitude 73° 26' W.
Webb Field; old Government field; ideal.

North Carolina

Bellhaven.—Latitude 35° 32' N., longitude 75° 37' W.
Seaplanes; no data.
Columbia.—Latitude 35° 55' N., longitude 76° 14' W.
Seaplanes; no data.
Danville.—Latitude 36° 01' N., longitude 79° 36' W.
Emergency field, on hilltop.
Edenton.—Latitude 36° 04' N., longitude 76° 35' W.
Seaplanes only; no data.
Elizabeth City.—Latitude 36° 18' N., longitude 76° 13' W.
Seaplanes only; no data.
Hamlet.—Latitude 34° 55' N., longitude 79° 39' W.
Emergency fields in open country around.
Hertford.—Latitude 36° 11' N., longitude 76° 28' W.
Seaplanes only; no data.
Kinston.—Latitude 35° 15' N., longitude 77° 34' W.
Hill Field; 500 by 1,000 feet; south of river; north of railroad.
Monroe.—Latitude 35° 00' N., longitude 80° 32' W.
Reported by the National Aircraft Underwriters' Association; no data.
Newbern.—Latitude 35° 06' N., longitude 77° 02' W.
Field of the Acme Film Co.; 150 by 700 feet; good when wet.
Oriental.—Latitude 35° 02' N., longitude 76° 41' W.
Seaplanes; no data.
Plymouth.—Latitude 35° 52' N., longitude 76° 44' W.
Seaplanes; no data.
Swan Quarter.—Latitude 35° 25' N., longitude 76° 20' W.
Seaplanes only; no data.
Washington.—Latitude 35° 33' N., longitude 77° 03' W.
Seaplanes only; no data.
Wrightsville Beach.—Latitude 34° 12' N., longitude 77° 48' W.
Seaplanes only; no data.

Ohio

Alliance.—Latitude 40° 55' N., longitude 81° 06' W.
Country Club; emergency field.
Canton.—Latitude 40° 48' N., longitude 81° 22' W.
Real Estate Company Field; 800 by 1,500 feet; bordered by streets.
Findlay.—Latitude 41° 03' N., longitude 83° 37' W.
Emergency; near old fair grounds; 1,000 by 3,000 feet; ideal.
Fremont.—Latitude 41° 20' N., longitude 83° 06' W.
Christy Farm Field; 700 by 1,200 feet; ideal.
Hamilton.—Latitude 39° 23' N., longitude 84° 32' W.
Emergency; fair grounds.
Ironton.—Latitude 38° 31' N., longitude 82° 40' W.
Field of the Rafusa Flyers (Inc.); flying instruction.
Kenton.—Latitude 40° 38' N., longitude 83° 36' W.
Emergency; fair grounds; ½-mile track.
London.—Latitude 39° 53' N., longitude 83° 26' W.
Field of the London Aero Club (Inc.), 1,500 feet square; hangar; supplies.
Ravenna.—Latitude 41° 10' N., longitude 81° 15' W.
Willard Brady Field; 750 by 1,200 feet.
Steubenville.—Latitude 40° 22' N., longitude 80° 35' W.
Emergency; country club; 1,800 by 300 feet.
Youngstown.—Latitude 41° 06' N., longitude 80° 37' W.
Olds Farm Field; 1,400 by 1,600 feet; near country club; ideal.
Zanesville.—Latitude 39° 57' N., longitude 82° 00' W.
Emergency; 900 by 650 feet; also ½-mile track.

Oklahoma

Altus.—Latitude 34° 38' N., longitude 99° 15' W.
80 acres; square; wheat stubble; near edge of town; altitude 1,500 feet.
Alva.—Latitude 36° 50' N., longitude 98° 45' W.
Emergency.
Anadarko.—Latitude 35° 04' N., longitude 99° 15' W.
Fair grounds track; 500 by 1,000 feet; good.
Arapaho.—Latitude 35° 32' N., longitude 99° 01' W.
Black Farm Field; 350 by 1,000 feet; good; altitude 1,500 feet.
El Reno.—Latitude 35° 30' N., longitude 97° 58' W.
Emergency; between city and country club; 48 acres; square; soft when wet.
Medford.—Latitude 36° 50' N., longitude 97° 43' W.
Field of the Grand Amusement Co.; 1,200 feet square; ideal.
Stigler.—Latitude 35° 15' N., longitude 95° 06' W.
Municipal field; 1,200 feet square; fair grounds; good when wet.

Oregon

La Grande.—Latitude 45° 20' N., longitude 118° 07' W.
Municipal; 320 acres near race track; ideal; good when wet.
Marshfield.—Latitude 43° 22' N., longitude 124° 12' W.
Municipal; 1,000 by 500 feet; good when wet; oil tanks north and south.

Pennsylvania

Bethlehem.—Latitude 40° 37' N., longitude 75° 23' W.
Emergency; 1,000 by 1,500 feet; 4 miles south of town.
Dauphin.—Latitude 40° 23' N., longitude 76° 57' W.
Emergency; 50 acres.
Hatboro.—Latitude 40° 10' N., longitude 75° 06' W.
Commercial; 16 miles north of town; along York Road.
Irwin.—Latitude 40° 21' N., longitude 79° 41' W.
Field of the Irwin Aircraft Corporation; 20 miles east of Pittsburgh; hangar.
Mechanicsburg.—Latitude 40° 13' N., longitude 77° 03' W.
Municipal; 30 acres.
Williamsport.—Latitude 41° 17' N., longitude 71° 04' W.
McCormic Motor Car Co.'s Field; 100 acres, along river; hangar.

Rhode Island

Pawtucket.—Latitude 41° 54' N., longitude 71° 22' W.
Emergency; no data.
Quonsett.—Latitude 41° 35' N., longitude 71° 25' W.
Emergency; state property; on bay, unlimited space.
Sandy Point.—Latitude 41° 40' N., longitude 71° 25' W.
Emergency; 5 miles east of Greenwich.

South Carolina

Beaufort.—Latitude 32° 36' N., longitude 80° 40' W.
Seaplanes only; no data.
Ducwest.—Latitude 34° 20' N., longitude 82° 24' W.
Aerial mail station; experimental station.
Georgetown.—Latitude 32° 22' N., longitude 79° 17' W.
Seaplanes only; no data.

South Dakota

Tyndall.—Latitude 43° 00' N., longitude 97° 51' W.
Field of the Tyndall Aeroplane Co.; 1,000 by 1,200 feet; hangar with circle on roof; good when wet.

Tennessee

Clarksdale (Memphis).—Latitude 35° 09' N., longitude 90° 00' W.
Field of the Memphis Aerial Co., near country club; hangars, etc.
Jellico.—Latitude 36° 36' N., longitude 84° 09' W.
Municipal; 60 acres; ideal; hangars, etc.

Texas

Blockners Ranch.—Latitude N., longitude W.
Near Rio Grande River; used by border patrol pilots.
Bracketville.—Latitude 29° 17' N., longitude 100° 18' W.
For Clark Drill Grounds; 4,000 feet square; ideal; good when wet.
Brenham.—Latitude 30° 10' N., longitude 96° 21' W.
Stone Meadow; 40 acres; ideal, good when wet; marker, hangar, etc.
Herne.—Latitude 30° 51' N., longitude 96° 31' W.
Elite Field; 35 acres, triangular; ideal; good when wet; hilly country.
Kernah.—Latitude 29° 32' N., longitude 95° 01' W.
Roberts Field; 1,600 by 1,800 feet; ideal; good when wet; east of creek.
Sabinal.—Latitude 29° 16' N., longitude 92° 26' W.

Digitized by Google

Emergency; ideal; good when wet; ¾ mile square.

San Diego.—Latitude 27° 45′ N., longitude 98° 14′ W.

Emergency; no data.

San Ygnacio.—Latitude 27° 00′ N., longitude 99° 19′ W.

Emergency; no data.

Taylor.—Latitude 30° 32′ N., longitude 97° 24′ W.

Tarner Pasture; emergency; 1,600 feet square; ¾ mile southwest of town.

Yoakum.—Latitude 29° 17′ N., longitude 97° 10′ W.

Emergency; on edge of town; 600 by 1,500 feet; along road; ideal.

Utah

Henefer.—Latitude 41° 01′ N., longitude 111° 30′ W.

Northwest of Coalville; emergency field.

Vermont

Brattleboro.—Latitude 42° 51′ N., longitude 72° 07′ W.

Emergency; good; marked with 100-foot circle.

St. Johnsbury.—Latitude 44° 26′ N., longitude 72° 01′ W. Emergency; along river.

Virginia

Cape Charles.—Latitude 37° 07′ N., longitude 75° 58′ W.

Seaplanes only; no data.

Washington

Everett.—Latitude 47° 58′ N., longitude 122° 11′ W.

Emergency; no data.

Kennewick.—Latitude 46° 13′ N., longitude 119° 07′ W.

Kelso Field.—Latitude 46° 09′ N., longitude 122° 55′ E.

Municipal; 160 acres; ideal; hangar, marker, etc.

White Bluffs.—Latitude 46° 45′ N., longitude 119° 28′ W.

Field of the Yakima Aviation Company; on Yakima to Spokane route.

West Virginia

Buffalo.—Latitude 44° 29′ N., longitude 81° 13′ W.

Aero Club Field; aerial taxi lines.

Huntington.—Latitude 38° 26′ N., longitude 82° 27′ W.

Commercial Flying Field.

Wisconsin

Alma.—Latitude 44° 18′ N., longitude 91° 52′ W.

Emergency; good fields on Minnesota side of river.

Buffalo.—Latitude 43° 45′ N., longitude 89° 29′ W.

Good cross country field.

Green Bay.—Latitude 44° 29′ N., longitude 88° 01′ W.

Aero Club Field; 1½ miles west along Fox River; 750 by 2,500 feet; ideal; good when wet; hangar and marker; seaplanes use river ½ mile away.

Minong.—Latitude 46° 07′ N., longitude 91° 48′ W.

Emergency; marked.

Pheasant Branch.—Latitude 43° 06′ N., longitude 89° 36′ W.

Good emergency field along railroad.

Stevens Point.—Latitude 44° 30′ N., longitude 89° 32′ W.

Fair grounds; ½ mile track.

Wyoming

Buffalo.—Latitude 44° 20′ N., longitude 106° 40′ W.

Emergency field; reported by the West Aero Corporation of Casper.

Casper.—Latitude 42° 51′ N., longitude 106° 20′ W.

Field of the Western Aero and Motor Corporation; Curtiss distributors; good when wet; hangar and supplies; altitude 5,400 feet.

Elk Mountain.—Latitude 41° 45′ N., longitude 106° 22′ W.

Emergency field; broad plains.

Greybull.—Latitude 44° 30′ N., longitude 108° 03′ W.

Emergency; no data.

Lander.—Latitude 42° 50′ N., longitude 108° 42′ W.

Emergency; no data.

Riverton.—Latitude 44° 02′ N., longitude 108° 22′ W.

Emergency; no data.

Shoshoni.—Latitude 43° 13′ N., longitude 108° 06′ W.

Emergency; no data.

Thermopolis.—Latitude 43° 40′ N., longitude 108° 13′ W.

Emergency; no data.

Worland.—Latitude 44° 02′ N., longitude 108° 58′ W.

Emergency; no data.

FOREIGN NEWS

BRITISH SAFETY FUEL TANK AWARDS

The British Air Ministry announces: The prizes in the Air Ministry Competition for Safety Fuel Tanks for aircraft have been awarded as follows:

First Prize—£1,400. The India-Rubber, Gutta Percha and Telegraph Works Company, Limited, Silvertown, London, E. 16.

Second Prize—£400. Imber Anti-Fire Tanks, Limited, West Road, Tottenham, London, N. 17.

Third Prize—£200. Commander F. L. M. Boothby, (R. N. Retired), "Overway," Tilford, Surrey.

The Competition was arranged in order to promote the evolution of a reliable type of fuel tank for Service and Commercial aircraft, which would reduce the risk of fire, due to crashing or hostile action, to a minimum.

Twenty-six entries were received for the Competition, which was open to the world, and eighteen different types of tanks were actually submitted for test.

The Judges appointed by the Air Council consider that the competition has resulted in the achievement of the objects for which it was instituted and has produced a type of safety fuel tank which, although capable of improvement in several minor respects, is available for immediate introduction on Service and Civil aircraft and which, for a slight increase in weight over and above that of the standard Service steel tank, gives almost complete immunity from fire, either in a crash or in action with enemy machines.

All the tanks tested, with a few exceptions, showed marked superiority in almost every respect over the standard Service steel tank now generally in use.

The Judges were: Group Captain E. F. Briggs, (Deputy Director of Research); Major B. C. Carter (Directorate on Research); Major J. H. Ledeboer (Directorate of Research); Mr. G. Cockburn (Accidents Investigation Branch); Major J. P. C. Cooper (Accidents Investigation Branch); Mr. H. Grinsted (Royal Aircraft Establishment).

The regulations governing the competition provided that each entrant had to submit two tanks for preliminary trials and that the three most successful competitors in the first stage should submit four more tanks for final trial.

Description of Winning Tanks

Details of the tanks submitted by the three winning competitors for the preliminary tests are as follows:

Tanks Submitted by Messrs. India-Rubber & Gutta Percha Co., Ltd., Silvertown, London

	No. 1	No. 2
Weight of tank	78.75 lbs.	81.25 lbs.
Capacity of tank	37.7 gals.	38.2 gals.
Weight of gallon capacity	.58 lbs.	.66 lbs.
Shape of tank	Cubical	

Each consisted of a welded sheet steel rectangular tank with no frame or baffles or any sort, but with each side slightly dished inwards, inserted in a detachable rubber case.

These tanks were slung in the fuselage by means of webbing.

Tanks Submitted by Messrs. Imber Anti-fire Tanks, Ltd., Tottenham, London

	No. 1	No. 2
Weight of tank	50 lbs.	51.5 lbs.
Capacity of tank	30 gals.	29.3. gals.
Weight per gallon capacity	1.66 lbs	1.76 lbs
Shape of tank	Elliptical	

The tank consisted of a light gauge tinned steel shell which was separated from the inside by a framework of aluminium tubing and light gauge aluminium baffle plates. After assembly the whole of the tank had been covered with india-rubber of a suitable thickness, and all joints vulcanized.

Tanks Submitted by Commander Boothby, Tilford, Surrey

	No. 1	No. 2
Weight of tank	33.23 lbs.	35.75 lbs.
Capacity of tank	58 lbs.	66 lbs.
Weight per gallon capacity	56.8 gals	53.7 gals.
Shape of tank	Cubical	

The tank consisted of an inner bag of 4-ply rubbered fabric capable of containing the petrol with an outer cover of rubbered fabric which was gas-tight. Non-inflammable gas was introduced into the space between the two shells and maintained under slight pressure. A drain pipe was fitted to the outer casing. The tank was fixed to the fuselage by rubber shock absorber and stringing and encased in 3-ply glued on.

Modifications for Final Tests

The three competitors qualifying for the final tests were required to submit four tanks of a type fundamentally similar to those entered for the preliminary trials, any minor modifications which it was desired to incorporate being previously submitted for the consideration and approval of the Judges Committee. This resulted in the following departures being made with the consent of the judges.

1. Messrs. The India-Rubber Co. incorporated the following modification:

(a) The metal of the fuel container was reduced from 20G to 26G.
(b) The capacity was reduced to within the prescribed limits.
(c) The tanks were internally coated with a lead deposit.
(d) Light gauge baffle plates were introduced.
(e) The method of attachment of the flap to the opening in the rubber cover was slightly modified.
(f) The attachment to the fuselage altered in detail but not principle.

2. Messrs. The Imber Anti-Fire Tanks Ltd., introduced compressed rubber buffers at the front of the tank and in place of metal straps and turnbuckles for fixing the end cradles, used leather thong.

3. Commander Boothby substituted a 3-ply outer casing in lieu of the outer fabric shell and was requested by the Committee to reduce the capacity of the fuel container proper to agree with the terms of the regulators.

Details of these modified tanks are as follows:

Tanks Submitted by Messrs. India-Rubber, Gutta Percha & Telegraph Works Co., Ltd.

	No. 1	No. 2	No. 3	No. 4
Weight of tank	57 lbs.	54.5 lbs.	57 lbs.	54.5 lbs.
Capacity of tank	29 gals.	29 gals.	29 gals.	28.8 gals.
Weight per gal. capacity	1.96 lbs.	1.88 lbs.	1.96 lbs.	1.89 lbs.
Shape of tank	Cubical			

Tanks Submitted by Messrs. Imber Anti-fire Tanks, Ltd.

	No. 1	No. 2	No. 3	No. 4
Weight of tank	52.5 lbs.	51.5 lbs.	50.5 lbs.	51.5 lbs.
Capacity of tank	30 gals.	29.7 gals.	29.7 gals.	29.7 gals.
Weight per gal. capacity	1.75 lbs.	1.73 lbs.	1.70 lbs.	1.75 lbs.
Shape of tank	Elliptical			

Tanks Submitted by Commander Boothby

	No. 1	No. 2	No. 3	No. 4
Weight of tank	36.5 lbs.	35.5 lbs.	33 lbs.	35.5 lbs.
Capacity of tank	31.5 gals.	31.5 gals.	31.5 gals.	31.5 gals.
Weight per gal. capacity	1.16 lbs.	1.13 lbs.	1.05 lbs.	1.13 lbs.
Shape of tank	Cubical			

Method of Testing

The method of testing the tanks in the preliminary trials was as follows:

Each tank was mounted in a wooden structure similar in construction to the fore part of the ordinary tractor small type aircraft. The concrete body formed to represent an engine was mounted in front of the tank. The structure containing tank and engine was released down an "I" section girder runway approximately 100 ft. high, so arranged that the body struck the ground at an angle of approximately 45° to the horizontal. It was originally intended to crash the structure on a concrete bed. It was, however, found necessary to modify the conditions and the bed was covered with a 2' 6" depth of sand. The conditions then briefly were those of the typical aircraft crash, the engine partially burying itself, the tank coming into violent contact with the engine. As, however, the fuselage structure at the moment of impact had attained a velocity—allowing for friction and air resistance—of approximately 50 m. p. h. the conditions were more severe than would prevail in a crash from which a human being could hope to escape with his life. The test was intentionally made thus severe in order definitely to reveal weakness or bad points in design.

In the final trains the following tests were imposed:

Two tanks of each type were submitted to acceleration and crashing tests and the remaining two to firing tests, the acceleration test being arranged to imposed stresses approximately equivalent to four times that due to gravity.

The tanks mounted in the fuselage structure were fixed to a pendulum raised to the requisite height and released by a trip gear.

A tank of each type submitted to this test was given two swings and was then placed on one side for 10 to 15 minutes at the end of which, from outside examination, nothing untoward bad occurred.

The crashing tests were carried out in a similar manner to that adopted for the Preliminary Tests with the exception that flints were substituted for sand on the crashing bed.

The tanks submitted to firing test were mounted to their fuselage structures and subjected to bursts of five rounds of Vickers machine-gun fire, composed as follows:

1 Armor piercing, 1 incendiary, 2 armor piercing, 1 incendiary.

Judging

A system of judging was adopted whereby each judge was enabled to record an independent opinion on a common basis. For the preliminary tests this system was on the following basis:

As regards weight, the basis of 100 marks was taken as representing a tank, which, complete with fittings, conformed to the specified weight of 1.75 lbs. per gallon capacity.

For each variation of a decimal point of this weight capacity ratio, 6 marks were added or deducted from the 100 marks.

In addition, as a means of correction in the case of tanks whose capacity was outside stipulated limits, the following formula was adopted.

Marks X Required Capacity

Actual Capacity.

Tanks received marks for the attributes in the following proportion:

(a) Crash-proof qualities	100 marks max.
(b) Remaining attributes	100 marks max.

(b) was divided up as follows:

Durability under Service conditions in the absence of accidents	25 marks
Indifference to extremes of temperature	25 marks
Adaptability of design to large capacities	10 marks
Simplicity of construction	10 marks
Adaptability of design to various shapes	10 marks
Accessibility of fittings	10 marks
Cost of production	10 marks

In awarding marks for the various attributes stated above, the ordinary mild steel service tank was taken as a standard.

This resulted in the following competitors being placed in the order named at the end of the Preliminary Tests:

1st. Commander F. L. M. Boothby; 2nd Messrs. Imber Anti-Fire Tanks Ltd.; 3rd India-Rubber, Gutta Percha & Telegraph Works Co., Ltd.

In the final tests the marking was made on the following basis:

100 marks maximum for each crash test	200
100 marks maximum for each firing test	200
100 marks maximum for remaining attributes	100
Total	500

The final result was:

1st, India-Rubber & Gutta Percha Co.; 2nd, Imber Anti-Fire Tanks; 3rd. Commander Boothby.

Each of these designs showed marked superiority in almost every respect to the standard service steel tank.

Other Tanks

Description of the unsuccessful tanks are appended below:

Digitized by Google

Tanks Submitted by Messrs. Beasley, Simms & Morris, 33, St. John's Road, Langley, Nr. Birmingham

	No. 1	No. 2
Weight of tank	78.5 lbs.	73.5 lbs.
Capacity of tank	35.6 gals.	34.8 gals.
Weight per gallon capacity	2.21 lbs.	2.11 lbs.
Shape of tank	Cylindrical	Cylindrical

These tanks were cylindrical and of all-metal construction. They consisted of a petrol-tight outer case containing an inner case with perforated ends, in two separate halves, suspended from flanges on outer case by means of very stiff compression springs.

The tanks were slung between cross pieces at each end which were connected together by longitudinal tie rods, clips being used to secure the whole to the fuselage.

Tanks Submitted by Mr. Bengtsson, 53, Ilford Hill, Ilford, Essex

	No. 1	No. 2
Weight of tank	80.75 lbs.	83.25 lbs.
Capacity of tank	33.8 gals.	33.5 gals.
Weight per gallon capacity	2.39 lbs.	2.49 lbs.
Shape of tank	Rectangular	

This tank consisted of two parts. The fuel container and an outside shell, the space between being filled with sheet cork.

Tanks Submitted by Mr. Bramson, Feeture, Girondo, France

	No. 1	No. 2
Weight of tank	60 lbs.	62 lbs.
Capacity of tank	38.2 gals.	36.1 gals.
Weight per gallon capacity	1.57 lbs.	1.71 lbs.
Shape of tank	Cubical	

These tanks were provided with but one outlet and one inlet connection and were of a very complicated construction; they had an inner compartment consisting of a duralumin frame covered with petrol-proof-doped silk over which was a layer of rubber "Caoutchouc mousse," which is a material of the sorbo-sponge type, but with very minute cells not in communication with one another; the rubber, therefore, was not porous. To ensure that if pierced the hole would seal up, this rubber was fitted under lateral compression and was held in place by a very fine mesh wire gauze.

This inner receptacle was slung in a metal framework by means of a wire net which was anchored to what eventually would be the four rear corners, another cover of fabric, caoutchouc-mousse, and a final one of fabric completed the tank. The last cover of fabric caoutchouc-fabric was kept a small distance away from the inner container by means of thin strips of wood, the space being utilized for CO_2 under pressure which is communicated to the inner portion of the tank by means of a small hole at the top.

The whole was mounted on four bearers which sat on the fuselage frame and were lashed in place by means of shock absorber elastic so as to allow a possible movement of approximately 4".

Tanks Submitted by Mr. Brooke, 9, Perkside Terrace, Cullingworth, Nr. Bradford

	No. 1	No. 2
Weight of tank	64.5 lbs.	61.25 lbs.
Capacity of tank	37.2 gals.	Due to leak from damage, capacity could not be taken.
Weight per gallon capacity	1.73 lbs.	
Shape of tank	Cubical	

The tanks were constructed with a rectangular inner metal tank built round a tubular framework and placed in the outer case, the surrounding space being packed with sheep's wool. Outside the other case was another layer of sheep's wool and around the whole were wound two layers of fine iron wire. The inner framework was also bound in each direction by iron wire. The tank was held in place by five tension springs on each of four corners.

Tanks Submitted by Mr. Delauny, 4 Rue Piedfort, La Havre, France

	No. 1	No. 2
Weight of tank	107.5 lbs.	Received in badly damaged condition and not tested
Capacity of tank	31.6 gals.	
Weight per gallon capacity	3.4 lbs.	
Shape of tank	Cubical	

The construction was similar to that submitted by Mr. Bengtsson, being a rectangular inner metal tank and outer case, with the intervening space packed with cork—see photograph 4685. This tank had but two connections, an inlet on top and an outlet at the bottom.

Tanks Submitted by Mr. Dickinson, Torquay House, West Cross Lane, Swansea

	No. 1
Weight of tank	92.5 lbs.
Capacity of tank	43.1 gals.
Weight per gallon capacity	2.15 lbs.
Shape of tank	Cubical

This tank consisted of an inner and outer tank, there being an air space of 1¼" between the two. This space was filled with lightly packed absorbent cotton and a chemical solution.

Tanks Submitted by Mr. Gibson, 16, Dyke Perade, Cork

	No. 1	No. 2
Weight of tank	50.8 lbs.	51 lbs.
Capacity of tank	30.9 gals.	30.9 gals.
Weight per gallon capacity	1.65 lbs.	1.65 lbs.
Shape of tank	Barrel-shaped	

These tanks were barrel-shaped and of all-metal construction; they were made of but one casing with two ordinary baffles and two truncated conical baffles, the base of each pointing to the end of the tank nearest to it and the small end joined to the two ordinary baffles.

Tanks Submitted by Captain Goete, Instituto Sperimentale Aeronautico, 5 Lungtevere, Michelangelo, Rome

	No. 1	No. 2
Weight of tank	51 lbs.	57 lbs.
Capacity of tank	30.1 gals.	31.1 gals.
Weight per gallon capacity	1.69 lbs.	1.83 lbs.
Shape of tank	Cylindrical	

They consisted of an inner tank of four separate compartments and an outer tank, the intervening space being filled with CO_2 or exhaust gas under pressure, approximately 3 lbs. per square inch. The four compartments were intercommunicable by means of special non-return valves which, in the event of a crash, were intended to shut off any broken compartment from the others. A small hole joined the outer space with the inner spaces, so enabling the petrol to be put under pressure.

Tanks Submitted by Mr. Hobbs, 268, High Road, Wood Green, London

	No. 1	No. 2
Weight of tank	75.5 lbs.	78.5 lbs.
Capacity of tank	40.4 gals.	51.4 gals.
Weight per gallon capacity	1.87 lbs.	1.53 lbs.
Shape of tank	Cubical	

These tanks consisted of an inner tank surrounded by cotton wool round which was wound a quantity of ordinary small mesh wire netting, more cotton wool, a netting of strengthening straps and the whole enclosed within a metal cover and more strengthening straps.

Tanks Submitted by Mr. Osborne, Fredensburg, Hammers Lane, Mill Hills

	No. 1	No. 2
Weight of tank	69 lbs.	69.25 lbs.
Capacity of tank	29.9 gals.	29.6 gals.
Weight per gallon capacity	2.32 lbs.	2.34 lbs.
Shape of tank	Cylindrical	

The tank was made of celluloid fitted with celluloid cage and baffle plates and strengthened with special celluloid girder work. It was enclosed in a specially built-up 3-ply cork container, which was then again enclosed in a special vulcanized india-rubber jointless cover.

Tanks Submitted by Mr. Penfold, c/o Sir John Jackson, Ltd., 53, Victoria Street, London

	No. 1	No. 2
Weight of tank	93.5 lbs.	99.5 lbs.
Capacity of tank	30.5 gals.	32 gals.
Weight per gallon capacity	3.06 lbs.	3.1 lbs.
Shape of tank	Cubical	

Each tank consisted of a rectangular welded aluminium container, the sides and back of which were corrugated, placed in a wire cage and tightly packed with asbestos fibre, and around the whole was an outer metal casing.

Tanks Submitted by Mr. Roberts, 32A, Mander Street, Wolverhampton

	No. 1	No. 2
Weight of tank	72 lbs.	72 lbs.
Capacity of tank	27.1 gals.	27.1 gals.
Weight per gallon capacity	2.65 lbs.	2.65 lbs.
Shape of tank	Cylindrical	

Each of the compartments of which the tank was constructed opened into a central tube within which was placed a liner capable of being turned so as to shut off the several compartments when the machine is descending in flames, so that in the event of a crash the fuel which is in the broken compartment only will leak and not the whole. The fuel container was enclosed in an outer shell, a liquid fire extinguisher being introduced between the two.

Tanks Submitted by Mr. Verhoeven, 118, Montignis, Chatilenau, Belgium

	No. 1	No. 2
Weight of tank	127.5 lbs.	124.5 lbs.
Capacity of tank	39.5 gals.	38.4 gals.
Weight per gallon capacity	3.23 lbs.	3.24 lbs.
Shape of tank	Cubical	

The tank consisted of inner and outer metal shells the space of approximately 1¼" between the two being packed with sheet cork.

The Giant Farman

The world's greatest biplane has just finished its final tests in the aerodrome at Orly and soon will commence trans-European flights. Probably it will be used in a new attempt to cross the Atlantic late this summer. It is of Farman construction, with four propellers and four 400-horse-power motors. The wing spread is more than 100 feet.

According to Aviator Boussotrot, its pilot, it will maintain a speed of 100 miles an hour while carrying twenty passengers and baggage—a total load in excess of seven tons. Although it was designed for passenger service, experts who examined it during the recent *salon d'aviation* declared it to be an ideal craft for bombarding cities from a great height in the event of another war.

Portuguese Airmen to Continue Flight

The Portuguese aviators, Capts. Saccadura and Coutinho, sailed May 9 from Rio Janeiro for St. Paul Reck from Fernando Noronha on board the Portuguese cruiser Republic.

The airmen took with them their new seaplane sent from Portugal on the steamship Bage, which was unable to land the machine at the Recks because of rough weather, bringing it on to Fernando Noronha. They expect shortly to resume their flight from Portugal to Brazil, cut short by the accident to their first seaplane in landing at St. Paul Rock last month.

Continental Air Couriers

The latest development in aviation is contained in an announcement that an Air Courier Service has just been put into operation between London and Paris. Mr. Ransley S. Thacker, a barrister who has for several years been interested in aviation work, is the one responsible for this new enterprise.

Mr. Thacker travels every other day by aeroplane to Paris, and returns in the same way next day. Shortly he may go to Paris and return on the same day. If the amount of business makes it necessary, and Mr. Thacker states that from his present experience it soon will be necessary, he will employ other couriers, who will be despatched by each of four daily services.

Mr. Thacker is prepared to transact business or to execute commissions of any reasonable nature, and we can imagine many and varied will be the missions which he will be asked to undertake.

Mr. Thacker's offices at Granville House, Arundel Street, Strand, are open day and night, so that instructions may for urgent reasons be made at any time during the night, and in order to develop this service to the full special night flying services will, it is proposed, later on be in operation; and in a short time it is hoped to have a Courier Air Service to Amsterdam, with connections to Berlin and Copenhagen, and also to Brussels, a direct service of couriers between London and Marseilles, and from Paris it will be possible to reach the most remote points by air.

The personal nature of this service is its *raison d'être*, and the commercial and legal experience and negotiating ability of its founder should be most valuable assets.

Mr. Thacker's charges vary from six guineas to ten guineas according to the nature of the transaction involved, but in any case it is considerably lower than the cost of sending one's own messenger.

It is shortly intended to open up offices in Paris, so that the business on that side may be developed also.

NAVAL and MILITARY AERONAUTICS

A. S. O. A. Sixth Corps Area

Short talks on the problems of the Air Service in the next war and the types of aeroplanes that are being developed to meet these problems were given at the May meeting of the Air Service Officers Association of the Sixth Corps Area, in Chicago. The problems were presented by Lieut. K. T. Price, A. S. O. R. C., and the descriptions of the machines and instruments now being developed were given by Lieut. Dallas M. Speer, A. S. O. R. C.

Following their remarks Major W. S. Wood of the reguar army spoke for some minutes on Customs of the Service, and the necessity of maintaining a high degree of discipline. He emphasized the importance of insistence on a smart military salute as a big factor in maintaining discipline and morale.

Air Service Offers Opportunity

How can I become an Airship and Balloon Pilot and at the same time obtain a commission in the U. S. Army Reserve Corps? No doubt many young men, recently graduated from College or about to obtain the coveted sheepskin this coming year, would be interested in such a proposition and would be glad to grasp the opportunity if they knew it existed. There does exist such an opportunity and it is not limited to college men alone, but in many instances, where a man is possessed of a good High School education, the curriculum of which includes sufficient mathematics and science, he may, upon satisfying the Examining Board as to his qualifications, be admitted to the Air Service Balloon School as a cadet and candidate for a Reserve Commission.

The Army Air Service has established schools for the training of Airship Pilots and Balloon observers. The object of these schools is threefold, first: to provide an adequate Officers Reserve Corps; second: to educate the young men of modern times in Aeronautics, past and present, and the possibilities of aeronautics in the future; and, last, but by no means least:—to promote the science of commercial aeronautics. This last object will have a far reaching benefit if it is carried out as contemplated. Even at the present time commercial aeronautics has become a leading economic factor in some countries, and this country has far greater possibilities, due to the government monopoly which the Army Air Service has on the Helium supply in the United States.

The question may here be interposed, "Why should this have any bearing on the possibilities of Airships?" Helium is a non-inflammable gas known to exist in the southwest part of the United States, particularly in Texas. Although, admitting the highly inflammable character of Hydrogen Gas, there have been very few Airships destroyed, the cause of which can be traced either directly or indirectly to Hydrogen. Nevertheless, the known characteristics of this gas had at least a moral effect on the promotion of Commercial Aeronautics which the discovery of Helium alone can eliminate.

Extensive investigations have been carried on to determine the extent of Helium resources and considerable money expended to develop the equipment necessary to place this gas on a production basis.

A maximum monthly production of Helium is now possible, amounting to approximately 1,000,000 cu. ft., and it is safe to predict that future production as required is assured.

Some of the recently designed ships have a lift of between fifty (50) and seventy (70) tons, over all, or over the weight of the ship itself. The use of Helium will make ships of this type practically as safe for transportation as the present over-land express. A line of ships of this type from New York to Chicago, to St. Louis, to Omaha, to Salt Lake, to San Francisco is not a mere possibility, but within, say, ten years, it will more than likely be an actual fact. The airship today is in the same category as the automobile of 1905, and how many automobiles were seen on the streets in those days? Those who have prepared themselves for the situation will find ample opportunity for utilizing their knowledge when the airship takes its place among the approved modes of transportation, and upon them will fall the responsibility of success or failure of commercial aeronautics, and to them will go the rewards when success is finally achieved.

It is impossible, in the brief space allotted, to go into all the possibilities of the airship. All that can be expected is to arouse your interest in this all-important subject to the extent that you will not let it rest without further investigating its possibilities and deciding whether or not the predictions are logical: for those who agree that they are, the Government offers a course of instruction leading to a Reserve Commission at the Balloon School, Ross Field, California.

The course at this school covers a period about of ten (10) months, and includes primary training in Airships. An advanced course in Airship work is offered at Langley Field, Virginia, for those who complete the Balloon Observers' and Primary Airship course at Ross Field. This advanced Airship course covers a period of about six months, and when the cadet graduates he is competent to handle any Airship in this country at the present time. This advanced course at Langley Field is not necessary to qualify for a Reserve Commission as it is given on completion of the Balloon Observers' Course. While retaining a Reserve Commission in the Air Service, the qualified Pilot may, as the opportunity presents itself, continue his flying training by taking periodical flights in the craft he is eligible to pilot.

Cadets are paid at the rate of $75.00 a month, exclusive of board, lodging and clothing. Applicants are desired between the ages of 20 and 25, preferably not over 30, and unmarried.

The 103rd Division

Progress in the organization of the 103rd Division, Air Service, has been fairly rapid considering conditions. Other Air Service units will be organized later. They will come under the head of "Army Troops." Names and qualifications are now being considered and set aside for the 436th Pursuit Squadron, Pueblo, Colorado; 437th Pursuit Squadron, Deming, New Mexico; 438th Pursuit Squadron, Santa Fe, New Mexico, and 439th Observation Squadron, Phoenix, Arizona. No Corps Air Service troops or lighter-than-air units have been allocated in this divisional area.

A keen interest in Air Service activities exists among reserve officers. All that have been interviewed are anxious to get hold of the "old stick" again and make inquiries as to the possibilities of a fifteen-day training period. Some of them have shown enough interest to write their Congressmen in Washington urging them to make sufficient appropriation for the Reserve Training Camp and to sustain the four million dollar appropriation.

Captain Charles A. Pursley, Air Service, was assigned to duty with the 103rd Division, Air Service (8th Corps Area) with station at Colorado Springs, Colorado. Two rooms in the Federal Building at Colorado Springs are set aside for the headquarters of this Division.

Captain Pursley, in his endeavor to obtain a suitable flying field at Colorado Springs or in the immediate vicinity, has invited recommendations as to a site from the Chamber of Commerce, civic organizations and citizens of the community. He has already inaugurated a publicity campaign.

Further Tests of MB-7

Pilots at Mitchel Field had the pleasure, during the week ending April 15th, of watching the little Thomas-Morse Monoplane MB-7 make test flights. Lieut. Flier, U. S. Marine Corps, the pilot, put the little ship over a measured course. The time for the flight has not been officially given out and the speed is not known. The pilot estimated, however, that the little plane made well over 190 miles per hour. This ship is a monoplane with a wing spread of only 16 feet, is powered with a 300 h. p. Wright motor, and consequently has a very high landing speed. Thus far the pilot has successfully flown the monoplane on numerous occasions without the slightest mishap.

Reserve Officers Visit Kelly Field

Reserve officers from all branches of the service visited Kelly Field on April 7th in charge of Major Thomas Duncan and Lieut. W. A. Morris. This party, about sixty in all, witnessed the formation of DH's and XBIA's. Major Reynolds, commanding officer of Kelly Field, guided the party down the line, describing each event that took place. Much interest was exhibited in the GAX and its possibilities. An exhibition flight in this plane was made by Captain Shea to demonstrate the psychological effect of a low, harassment plane on ground troops. All left with a feeling that such a plane would be rather disturbing.

April Flying Record at Carlstrom Field

Records of the Flying Office at Carlstrom Field show a total of 2,439 hours and 50 minutes flying time for the month of April, 1922. This time was flown in the following type ships: JN4-6 Curtiss, DH4B, Vought, Spad, Thomas Morse and Nieuport.

ELEMENTARY AERONAUTICS and MODEL NOTES

The Design of Model Propellers

An outline of the practices of the Illinois Model Aero Club

THE propellers on a model aeroplane transform the energy stored in the rubber into mechanical energy for overcoming the drift or the resistance of the machine as it passes through the air. The amount of thrust given by the propellers has very little effect upon the speed of the model as the formula, $speed = (weight\ \% \div surface \times Ky)^{1/2}$, will show. The excess in thrust, i. e., the thrust that is not directly used in overcoming the drift of the model, forces it to climb. As Ky or the lift coefficient of a given model wing varies but very little during its flight, the speed of a given model is nearly constant throughout its flight, the excess in thrust at the beginning causing a quick rise then, providing, of course, the model is properly powered.

The area of the model wing should be reckoned from the speed of the propellers rather than vice versa. The frame and propellers should be first built and assembled; then as much rubber put on the frame as it will stand for all-around flying. (And remember a flying model is not doing its best unless the frame is loaded till just below the breaking point with rubber.)

Then the rubber should be wound full and the average R.P.M. until the rubber is about one-half unwound taken. This used in the formula $R.P.M. \times Pitch \times 60 \div 12 \times 60 \times 100 = 8$ (*total weight divided by x or the unknown area in square feet*) ½ will give the area needed for the propellers used.

The aim in the design of a model propeller should be efficiency. Up to a certain extent, with all other things equal, the larger the propeller the more efficient it will be, for the end loss grows relatively smaller as the propeller grows larger, and also the larger propeller is not so likely to be working in air disturbed on a previous revolution.

Unfortunately, however, there are some serious limitations as to the size of model propellers. They cannot be too large on a twin-push or the frame will be so wide that the efficiency gained in propeller design will be lost in the inefficient angle of thrust. Slight overlapping of the circles described by the propeller blades on a twin-push is advisable, but must not be overdone. On a hydro, the larger the propeller the higher the machine must set from the water, and the hydro model that is set high above the water is not likely to be a record breaker. In this connection a four-bladed propeller, while a hard thing to construct and not efficient unless of a high pitch, has nevertheless made an efficient model.

For the same reason that propellers should be large, the blades should be narrow and the same limitations prevail. The tips, where possible, should be narrow with the widest part of the hlade about 65% of the distance to the tips. Sweeping tips are advisable except that such tips usually split easily.

In the securing of efficiency the blades of a propeller must have a true or constant pitch; that is, the pitch must at any point on either blade be the same, for when the propeller turns around every part of the blade should have a tendency to go forward exactly the same distance. To make this possible, the angle of a hlade must become greater and greater as the hub is approached, reaching an angle of 90 degrees at that spot, for as the blades turn about the tips travel through a larger circle than points nearer the hub and such points must go forward at a proportionately greater angle to keep in pace, so to speak, with the outer part of the blade.

In a carved propeller there are several ways of getting a true pitch, but the easiest and most satisfactory is to carve the propeller from what is known as a Wright blank, patterned from the original Wright aeroplane propeller.

That the pitch of a propeller carved from such a blank would be true and constant can be easily shown. The formula for calculating pitch, taking the measurements from either end of the blank, is, *pitch equals phi-D thickness divided by the width.* Then if the pitch is true P must equal the same thing for any spot on either blade. Let X be the distance of any spot from the center, then the pitch at that spot would be $pitch = phi\ (d - 2X)\ (thickness \div (W\text{-}D - 2W.\ X^3\!/_4D))$. Putting the values for P equal to each other, then, $phi\ D\ T/W = phi(D - 2X)T \div (W\text{-}D - 2W\ X/D)$, which, being an identity, shows that a propeller carved from a Wright blank will have a true helical pitch.

However, if the builder wishes to construct a bentwood propeller, then the pitch must be made constant by a different method. Finding the correct angle at a number of spots on each blade by means of a geometrical construction is perhaps the easiest method. The proper angles once found are transferred to the propeller by means of templates.

It must not be understood that either of the above methods will give an absolutely true pitch in practice. Only an approximation to a true pitch can practically be obtained because of variations of the lift and drift coefficients, i. e., parts of the blade nearest the hub which revolve at a high angle are less efficient than the part farther out which revolves at a lower angle. Some of this departure from the helical can be obviated by increasing the depth of the section as the hub is approached, which is usually done anyway to obtain the desired strength.

The size of the propeller to be used on a given model should be estimated from the size and strength of the frame. On a twin-push the propeller should be as large as the frame permits with a slight overlapping. On a tractor the diameter of the propeller is left to the discretion of the builder. The pitch of the propeller on a twin-push is usually about 1½ times the diameter, and a little less on a tractor, although this is largely left to the choice of the builder. Some model builders always carry two sets of propellers with them for each model, one set having wide blades and the other set having narrow blades, while the pitch and diameter are about the same; this allows them to make the most of the existing conditions at the flying field.

As has been stated, the pitch of a propeller can be found from the dimensions of the block from which the propeller was carved by means of the obviously true formula: *pitch equals phi-D.* $(T \div W)$. In laying out a blank from which to construct a propeller, a certain pitch is usually desired, as is the diameter and width (for whether narrow or wide blades are desired should have been previously decided). Then the thickness alone is lacking. Transposing, we obtain: *T equals phi*: $W \div$ *phi-D.*

Of the general methods of constructing propellers, i. e., carving and bending, carving is the method now in vogue, although the British have had some sensational success with the other method.

The Illinois Model Aero Club

By Joseph Lucas

The Illinois Model Aero Club was founded during January, 1912, to popularize and study the science and art of aviation through model aeroplanes. This organization was one of the first madel aeroplane clubs to be organized in the world, and it has advanced steadily while many other similar organizations formed later have fallen by the wayside. At present it is in its ninth year of successful operation.

Since the first model contests were held early in 1912 up until the present time the club has progressed until it now holds nine of the ten world's records recognized for models of the rubber-driven type. In addition to holding these records the club is the permanent owner of the Villard Trophy as a result of having won the National Model Aeroplane Competition three consecutive times. This competition consisted of a series of contests each year in which clubs from all over this country were entered. Practically all of the individual prizes, as well as the Villard Trophy, were won by members of this club.

From these facts it is easily seen that the Illinois Model Aero Club has been very successful in its work, and it is desired to continue this success by helping all who are interested in model flying or in aviation in general, and by popularizing this game throughout the world. It must be brought to as high a standard as possible and gain that high degree of respect and consideration which it deserves. There never was a mechanical field which held so much fascination for boys, not even the wireless craze, that model building and flying has not surpassed. There can be no doubt that all its effects are beneficial, not only to the brains and hands of the model builder but to those leaders in the aviation world who welcome suggestions by model experimenters.

RADIO DIGEST

Radio Tells Aircraft Altitude

The uses to which wireless is being put on aircraft apart from ordinary communication are yearly becoming more impressive. The latest idea is to use wireless for informing the aeroplane pilot of his exact height above the ground.

Two methods are under consideration. The first makes use of the noise of the engine, which is caught in a series of microphones on the ground, enabling the height of the machine to be ascertained and transmitted to the pilot by wireless. In the second use is made of a proximeter, acting upon the principle that when electrical oscillations are set up in a circuit the frequency of these oscillations depends upon the electrical capacity and inductance of the circuit.

Radio to Join Five Countries

On returning from the International Radio Conference yesterday Edward J. Nally disclosed the fact that a new radio service that will link five nations together was one result of the gatherings in Cannes, Paris and later in London.

The conferences were carried on under the auspices of the Commercial Radio International Committee, and this agreement has been made between representatives of companies of England, France, Germany, United States and South America.

The new circuit will be operated in New York, Paris, London, Berlin and Buenos Aires. Mr. Nally, who is the president of the Radio Corporation of America, came back on the steamship Homeric after several weeks abroad attending the conferences. He told *The Evening World* that many important questions affecting the development and operation of wireless were considered and satisfactorily settled; in particular, the questions dealing with the extension and development of worldwide telegraph and telephonic communication.

The first of these new international services will be in Argentina, where a super-powered station is now in course of construction and which will be completed soon. It will be located near Buenos Aires and will be capable of transmitting and receiving simultaneously with the stations to be erected in this city, Paris, London and Berlin.

Another conference will be held by technical experts of committee in Berlin late in June to conclude the worldwide connection of other countries by wireless.

Mr. Nally said that the people in Europe are intensely interested in the development of the radiophone and broadcasting service in the United States. Owing to existing laws their many difficulties will have to be overcome by several of the governments before broadcasting is done on the same broad plane as in the United States.

Progress Rapid in Sea Radio

There has been a great change in the mode of communication to and from steamships through the radiophone discovery. The first transatlantic steamship upon which a wireless telegraph apparatus was installed was the St. Louis of the American line. It was installed by Guglielmo Marconi, the inventor, who superintended the work from the top deck in November, 1899, when the St. Louis was making her fifty-second voyage eastward toward Southampton. Communication with the English shore was established when the vessel was sixty-six miles from the Needles. Today great wireless towers are able to flash messages half way around the world by telegraph and every modern steamship is equipped with both the wireless telegraph and telephone apparatus.

Some of the larger vessels are enabled to receive messages in the telegraph code from a distance equal to the width of the Atlantic, but for sending their transmitters will not carry so far. However, with the present telegraph system, a traveler during a transatlantic voyage may communicate with the shore at any time that other ships are willing to relay messages.

That this same system may be further embellished by the radio telephone is now the hope of the various big broadcasting companies who are making the tests with both incoming and outgoing steamships and at the same time making history.

A Warning to All Radio Phone Fans

If you are a radiophone fan—and if you aren't you must be the man Bob Davis once described as "the most extinct of his species"—if you are one of the growing thousands who get companionship, knowledge and recreation out of the little black box, be prepared for an explosion. While you are about it better get prepared for a lot of explosions. They'll be coming along with the first hot weather, says Ernst F. W. Alexanderson, chief engineer of the Radio Corporation of America, in an article, "The Imp in the Radio Box," in *Collier's Weekly* for May 13. He warns that these explosions will raise so much ruction that the radiophone owners switching in for their nightly concert will feel "as if they had been put into a steel tank against which a husky regiment of boys was throwing tons of everything, from buckshot to paving stones."

These explosions, Mr. Alexanderson explains, are first cousin to the lightning. Their other name is static. Mr. Alexanderson writes:

"This summer the new owners of radio apparatus will have to learn the fact which amateurs have long known—that their sets will give only about half normal service during hot weather. It will depend a good deal on the location of the receivers with reference to the sending stations. Those within about twenty miles of the broadcasting centers should be able to hear signals and conversation and music most of the time, though often with a background of rumbles and cracks. Those farther away will hear proportionately less. It will be seldom indeed that it will be possible to receive from stations several hundred miles away, as has been done by many during the winter. This is true of radio receivers of all kinds. The static imp plays no favorites."

But there are ways to beat the static imp. One is to run a straight wire about 400 yards long (which corresponds with the radio broadcasting wave length) in the general direction of the station from which signals are to come. If you cannot command such magnificent distances for your aerial you can rig up one of the "loop" type—a long wire wound several times around a vertical wheel, and turn the rim of the wheel toward the sending station. Much can be accomplished also in eliminating static by sharp turning.

Most of us, Mr. Alexanderson says, will have to wait for cold weather to come again before we are real happy with our radiophones, but he promises that by the time another summer comes around the radio experts will have made a big advance toward the solution of radio's biggest present problem.

Radio Set Acts as Barometer

Many experienced radio enthusiasts are able to predict, with a fair degree of accuracy, the advent of cloudy or rainy weather. When the static in the air is particularly heavy, which is evidenced by a loud hissing sound in your receivers, you may be quite sure that bad weather is close at hand. This may be observed on small crystal sets as well as on more elaborate apparatus.

Europe Interested in U. S. Radio Progress

The people of Great Britain and the countries of Europe are viewing with great interest the strides made by the United States in the use of the radio telephone and are preparing to develop the newest wireless invention on a similar scale, according to Edward J. Nally, who is president of the Radio Corporation of America and who returned to the United States from abroad this week.

Broadcasting will encounter a number of difficulties in Europe which have not faced the pioneers in the United States, Mr. Nally said, because of the small size of some of the nations, the varying languages and laws of restriction which may be made in respect to sending messages across national boundaries. Great Britain has already started broadcasting, however, as have France and Germany. The latter country has already established an extensive financial and general news service, which is being broadcasted to a number of places in Holland, Denmark and other of the smaller neighboring countries.

"The people of the European countries," said Mr. Nally, "are extremely interested in the reports being published there of the surprising development and extension of the radiophone in the United States, and are preparing to deal with it. Owing to existing laws there are many difficulties to overcome in the way of limiting regulations and restrictions with probable interference among the several countries, however."

Mr. Nally attended the conferences of the Commercial Radio International Committee, which were held in Cannes, Paris, and later in London. Representatives of the Radio Corporation of America, the Compagnie Generale de Telegraphie sans Fils of France, the Gesselschaft fur Drachtlose Telegraphie M. B. H. of Germany, and Marconi's Wireless Telegraphy Company, Ltd., of Berlin.

The head of the Radio Corporation said that plans were under way for the immediate construction of wireless stations in a number of localities, particularly in South America. Through agreement between the four companies of the Inter-

Digitized by Google

national committee service for commercial purpose was to be improved materially in the near future. One of the large stations is already in the process of construction in Argentine and will transmit and receive from similar places in New York, Paris, Berlin, and London.

"The conference," said Mr. Nally, "considered the extension and development of wireless communication generally and it was agreed that, in order that commercial wireless telegraphy and telephony should be developed to the best advantage in the interests of the public and of international commerce, in the construction of wireless stations every care must be taken to avoid interference. It was decided that the four companies shall not erect and will not view with favor the erection by others of any stations which will entail the radiation of harmonics or secondary waves beyond the agreed distance outside the limits of the definite wave bands allotted to each particular station."

Business Men Form National Radio Council

A National Radio Chamber of Commerce has been organized for the purpose of remedying some conditions which have arisen in the radio industry as an inevitable result of the over-rapid growth of the industry in the past months and to group together manufacturers whose radio products are of such dependable character as to maintain favorable public opinion toward the radio industry.

It is stated that eligibility to membership will depend, not on the size of a concern, but rather upon the quality of the product manufactured. The original group consisted of about fifteen manufacturers. New members will be added to this body by invitation, to the number of about twenty additional concerns whose business standing and products are known to be of a high order. The quality of the products of candidates for membership will be determined upon by a board of five members.

The Radio Chamber of Commerce plans shortly to organize a Credit Bureau for the interchange of credit information.

At a meeting recently held in New York plans were outlined and the following officers elected:

President, Alex Eisemann of the Freed-Eisemann Radio Corporation; first vice-president, Charles Keator of the De Forest Radio Telephone and Telegraph Company; second vice-president, William Dubilier of the Dubilier Condenser Company; secretary, Frank Hinners of the Home Radio Corporation, and treasurer, Joseph D. R. Freed of the Freed-Eisemann Radio Corporation.

Women Form Radio League

The Women's Radio League of America, Inc., held its first annual meeting on Tuesday evening, May 2, in room 907 Y. W. C. A. Building, Fifty-third street and Lexington avenue.

The following officers were elected: President, Miss Abbie Morrison; vice-president, Mrs. Eleanor G. Regan; secretary, Mrs. J. Koch; treasurer, Miss Elizabeth Rhodes.

The regular meetings of the league are held on the first and third Tuesday evenings of every month at the above address. Code practice for those who wish it is at 8 p. m., business meeting at 8:30 and the speaker of the evening at 9.

At the next meeting, on May 16, A. H. Hebert, an official of the American Radio Relay League and member of the second district executive council, will speak on "Co-operation and Organization."

All women interested in radio are invited to attend these meetings, and if desired courses in radio telegraphy or telephony can be arranged for.

State Police to Get Radio

The superintendents of state police of the states of New York, Massachusetts, Connecticut, Pennsylvania, New Jersey and Michigan, in conference in New York, seriously discussed the advisability of equipping their stations with radio systems. A system has already been installed in Pennsylvania which will be officially tested this week.

Book Reviews

Two very good books have been sent in this week by the Technical Book Company, New York. Both books are written by an author whose technical works have had national indorsement, James R. Cameron. The first book is "Radio for Beginners." This volume treats in an understandable manner the subject of radio, from the theories of elementary electricity to the adjustment and operation of the different types of modern receiving sets. A number of outfits being supplied by the larger radio concerns are described in detail, and instructions for getting best results out of these sets are also given. The other book is the "Radio Dictionary," a little book containing a wealth of material. All the terms usually met with in radio, electricity, and allied subjects are simply defined. Both books would make a valuable addition to any beginner's library.

The James A. McCann Company, 188 West Fourth street, New York, offers a very good book at a very reasonable price. It is "Amateur Radio," by Maurice J. Grainger, radio expert, formerly with the Westinghouse Electric Company and the United States navy. It opens up with the fundamentals of electricity and leads on to practical operation and theory of the most advanced amplifier sets. Each piece of apparatus is explained in an understandable manner. Near the end of the book is given a glossary of the most important radio terms, and also valuable information concerning time signals and radio laws and regulations.

A little book of merit, "Radio Made Plain," by John D. Haskell, is published by the Radiox Associates, 222 Charles River road, Cambridge, Mass. This little book presents in question and answer form a most useful and interesting mass of data needed by the newcomer in the radio game. Equipment, installation, and use and radio terms are treated in regular order. A quarter buys it.

Proper Tuning Big Factor in Radio Receiver

Tuning of the receiving to the beginner is a thing that has a lot of mystery connected with it. The question has been asked, "How do you know where to pick up the desired signal?" There is no way to tell on a set that the amateur is not familiar with. But, after the set has been in operation for a little while, the beginner will soon learn exactly where to pick up the desired signals. Most sets have dials on them that are divided off into 180 degrees with the numbers engraved on them for every ten degrees. These numbers have nothing whatsoever to do with the wavelength of the station, but are simply put there to enable the operator to remember easily at what point a station will be heard. Usually the lower numbers represent the short wavelengths and as the dial is turned about the longer waves will be heard.

With most sets it is a very simple matter to soon learn exactly where the desired signal may be heard, and the set may be left in the same setting all the time if it is used just for receiving the broadcasting. In other words, the set is tuned to receive the music from W J Z, and there is no necessity to move the knobs again unless other stations are wanted.

The theory of tuning is a long and complicated study, and a few words on the subject may clear up a lot of misinformation. In the first place, every transmitting station has a certain wavelength upon which the transmitted signals or voice is transmitted. The receiving set, however, is capable of receiving several wavelengths by turning the knobs about. A transmitter can also be made to transmit on several wavelengths, but cannot be tuned as fast as receiver. When your receiving set is tuned to receive a certain transmitting set it is in resonance with the other station. A simple way to explain this is to say that the wave lengths are very nearly the same. This is accomplished by adding or subtracting a certain number of turns of wire in the coils and thus equalize the wavelengths of the two stations. By the addition of different pieces of apparatus it is possible to make this tuning very sharp, and there are some sets that will receive the desired signals only. However, these sets are very expensive and the operator has to be an expert. The average amateur set will not tune sharp and a great deal of trouble has been caused by some beginners filing complaints about some amateur spark transmitter. Usually the spark transmitter is tuned to a sharp wave and is operating legally, while the beginner's set is the one that is at fault, as it is incapable of sharp tuning. If more beginners would study up on these facts before purchasing a set there would not be so much interference. Many amateurs have home-made receiving sets with which it is possible to sit and listen to W J Z all the evening without hearing a single interfering station.

Of course, there are certain cases where it is impossible to tune out the unwanted station with any set. Some amateurs are unfortunate enough to be located very near one of the naval or ship stations, and it is impossible to do any tuning, owing to the close proximity of the transmitter. When buying a set ask for a demonstration showing the selectivity of the set, as by doing this the beginner will save himself a great deal of trouble in the future.

Lift and Drag Effects of Wing-Tip Rake

This report (No. 140) by A. F. Zahm, R. M. Bear, and G. C. Hill of the National Advisory Committee for Aeronautics deals with a description and report of tests carried out at the Washington Navy Yard on models of the RAF-6, Albatross, the Sloane aerofoils to determine the effectiveness of the conventional wing-tip rake in improving aerofoil characteristics. Two degrees of rake were tested on each model; the trailing edge being always longer than the leading edge. The results are compared with the values computed by standard formulae in use at the time the tests were conducted.

A copy of Report No. 140 may be obtained upon request from the National Advisory Committee for Aeronautics, Washington, D. C.

Personal

Major B. M. Atkinson, A. S., returned from the Letterman General Hospital on May 4th, and again assumed command of Mather Field.

Avro with 110 H.P. Le Rhona or 130 H.P. Clargat and DH-6 with OX5, OXX6, 95-110 Anzani or 6 cyl. Benz.

2 SEATERS—JN'S $650.00 UP
Mercedes, Isotta or Hiso Standards $2500.00

NEW AVROS—$1250.00 to $1500.00
Single Seater—45 Anzani—80 Le Rhone
$450.00—$650.00

3 SEATER M.F. BOATS—HISPANO—$2000.

ALL PLANES EXCEPT SINGLE SEATER AND JNS NEW

What is a DH-6? It is an English training plane huilt for OX-5 motor. Span 36 ft., chord 6 ft., surface 418 sq. ft. Lands 30-35 m.p.h. and climbs 2000 ft. in 5½ minutes, loaded. We remodel them making two cockpits instead of one long one, instell a new gas system and use forward stegger insteed of back stagger, giving the ship a much better performance and appearance. It has about twice the factor of safcty of a Canuck, lands 10 to 15 mi. slower than a JN, is more steble and easier to fly than a Standard Jl end will get in and out of even smaller places than an Avro. It has no equal for harnstorming, instruction or generel pessenger work. Plenty of spares—cheap.

Our ships and prices must he right. 37 of 4 different makes sold since Jan. 1st., 1922.

DEALERS—Let's get together. We will work with you.

Learn to Fly

Aviation is making such strides that it needs more men right now

You Can Learn To Fly

I can teach you how to become a successful pilot in a short time. My course is so arranged that you get only the things you need to make you a good aviator.

The Diggins Extension Course

is up-to-date, teaches you what you must know to become an expert flyer. This course is written by competent instructors right on my flying field. It is kept right up to the minute—all new developments in aviation are included. That is why it is recognized as the most complete and practical course offered today. My course saves you time and money because it prepares you at home so that you are ready to begin flying the day you arrive at the flying school.

Superior Points of the Diggins School

1. The Diggins school is the oldest, largest and most complete commercial aviation school in America.
2. The Diggins school is located in Chicago, the center of Aviation.
3. Living quarters and free employment service are maintained for students.
4. Diggins guarantees to make you a pilot.
5. Diggins' pilots get top notch salaries.
6. References, any aero club in America.

AERIAL AGE WEEKLY
280 Madison Avenue New York

(Concluded from page 243)

They will require only a few minutes' attention about the time the flier is scheduled to pass overhead.

The control stations at Curtiss Field, Bellefonte, Pa.; Cleveland, Ohio; Bryan, Ohio; Chicago, Ill.; Iowa City, Iowa; Omaha, Neb.; North Platte, Neb.; Cheyenne, Wyo.; Rock Springs, Wyo.; Salt Lake City, Utah; Elko, Nev.; Reno, Nev.; and San Francisco already have been equipped with radio stations.

All that is necessary now is to equip the planes with a small, light type of radio direction finder to pick up the impulses sent by the fields. The pilots in addition will have radio receiving sets in their cockpits so that they can get news of any bad weather or unusual conditions they are running into. Thus equipped the eighty remodelled De Havilands of the service will be able, night and day, to reel off their two miles a minute steadily and surely between the Atlantic and the Pacific.

Gentlemen:

We feel it is only fair to let you know of the wonderful success we have had with Lakeside Aviation Oil.

After making dynamometer and short flight tests at Keyport we decided to make a real flight test on Lakeside Aviation Oil, so we used it on part of the record-breaking flight of the Aeromarine Cruiser "Santa Maria" between Chicago and Key West via the Mississippi River.

This Cruiser encountered most unfavorable flying conditions on the lower Mississippi, where Lakeside showed itself far superior to any of the many oils we had used. The consumption of Lakeside Aviation Oil over a fifty-hour period was less than half of the best oil we had then found.

Needless to say, we were very much pleased and have used Lakeside Aviation Oil in all our extensive operations, with the same wonderful results. We have proven the truth of your slogan "COSTS LESS PER FLYING HOUR".

Thanking you for insisting that we try out your oil, we remain

Very truly yours,
AEROMARINE AIRWAYS, Inc.

GOODYEAR IS READY TO HELP

Copyright 1922, by The Goodyear Tire & Rubber Co., Inc.

As larger and more powerful ships take to the air, Goodyear's alliance with aviation is strengthened. For an experience as old as the airplane itself enables Goodyear to anticipate and fill the needs of progressive aircraft builders.

For example, Goodyear Airplane Tires are now available in sizes up to 44 x 10 inches, the largest being designed to care for a load of 6,000 pounds per wheel. And doubtless there will be bigger Goodyear Airplane Tires in the near future.

Goodyear's steady effort to assist the advancement of flying is not limited to the development of Airplane Tires, or other essential equipment for heavier-than-air machines.

For no mention of the progress accomplished in balloon or dirigible work can be made without thought of Goodyear's aid and firmly established position in this important branch of aeronautics.

The Flight Around the World

MAJOR Wilfred Blake and Capt. Norman Macmillan set forth on their historic around-the-world flight on May 24. The Aircraft Disposal Company has, with commendable sporting spirit, placed four machines at their disposal, and the project appears to give fair promise of success. The machines to be used, although not of new types, have stood the test of time, and, given reasonable luck, the aviators should have a very good chance of getting through. Although as a sporting effort the use of a single machine for the entire flight would have been more spectacular, the employment of four machines, of three different types, will be a much closer representation of the actual conditions which will obtain when we come to run really long-distance services, and from that point of view is, perhaps, of even greater practical value.

Two of the machines will be DH9's (three-seaters) with Siddeley "Puma" engines. One will be a Fairey twin-float seaplane of the famous F. III type, which has a Rolls-Royce "Eagle" engine, and the fourth will be a flying boat of the F type.

In the main, the route to be followed by Major Blake and Captain Macmillan will be the same as that planned by Sir Ross Smith. The last "leg," however, will be different from that planned by Sir Ross Smith, who, it will be remembered, had intended to make the Atlantic crossing direct from Newfoundland to Ireland if possible, or, as an alternative, fly from Newfoundland to London *via* the Azores and Portugal. Major Blake and Captain Macmillan intend to follow the northern route *via* Greenland, Iceland, the Faroe Islands and Scotland, which will considerably shorten the non-stop stages that have to be negotiated. At the time of year when it is expected to cover this part of the flight the weather in the northern latitudes should be favorable, except for local fogs, and by taking this route the strain on the engines should be considerably reduced.

The manner in which it is intended to use the various machines is as follows: One of the DH9's will be used for the journey from London to Calcutta. Here the aviators will change over to the Fairey F. III seaplane, which will take them around the coast up to Kamchatka and across to Alaska. Here another DH9 will await them, on which the flight across Canada and America to New York will be accomplished. From New York or Newfoundland the last stage, across the northern part of the Atlantic, will be attempted in the F. boat.

This, in very brief outline, is the plan of Major Blake and Captain Macmillan, and, barring unforeseen accidents, the scheme promises success. That difficulties will be met and obstacles have to be overcome goes without saying, but there is certainly a very good chance of getting through. All the machines to be used, although of fairly old type, have been proved by years of flying under all sorts of conditions, and should be capable of the stages on which each is being used. The engines also have proved themselves in numerous long-distance flights, and may be expected to uphold the reputation already established. Captain Macmillan is one of our best pilots, and has had experience of a number of different types of machines.

Altogether, the scheme looks promising, and we wish the gallant aviators every success in their very sporting attempt.

Dine in London—Sup in Paris

THE night flying route between London and Paris was recently inaugurated by Major-General Sir W. S. Brancker, Director of the Air Ministry, and Lieut.-Col. Lyster F. Blandy, in charge of communications for the Ministry. The new service, using Handley Page machines, will be known as the Starlight Airway Route, and promises to be another historic step in the progress of aviation.

When the route is regularly operated, which will be soon, it will be possible for a party to dine in the West End of London and get a midnight supper on the hill of Montmartre in Paris. It will follow the regular continental air path and signal lights will be aglow at all the airdromes along the line.

Discussing its possibilities, Col. Blandy said: "Night flying from London to Paris is sure to come as an established service because its advantages over the present means of transport by rail and sea are obvious.

"By this means we hope in every way to develop trade, and we believe that passengers will come to regard the starlight route as the ordinary way of getting there. Certainly it will be the quickest and the pleasantest; and, if not the safest, it will at least be equally safe as any other way. It should appeal strongly to business men who cannot afford to waste a day or a night with its inconveniences of traveling. We are demonstrating to the public the extraordinary possibilities of night flying."

THE NEWS OF THE WEEK

Propose Air Freight New York to Chicago

The War Department is asking information as to the probable volume of traffic available for the support of an air line for commercial transportation between New York and Chicago. The Government disires to promote the commercial use of aeroplanes so that the development of aeronautics in this country may keep pace with the advance in other countries. Congress is now considering two phases of the subject—air mail service and commercial transportation by aeroplanes.

Major General Mason M. Patrick, Chief of Air Service, in a letter to William Fellowes Morgan, President of the Merchants Association, requests that the association aid in obtaining information sought in the proposed extension of air lines with Government co-operation.

"In accordance with the announced policy of the President and of the Secretary of War to encourage the early development of civil aeronautics," says the letter, "this office has under investigation the possibilities of civil aircraft operating as a transportation agent along organized routes. In particular, an organization to permit daily overnight transportation between the industrial communities of New York and Chicago is being considered.

"It is of first importance to determine as accurately as possible what the average daily volume of traffic would be which would utilize overnight air transportation if it were so established that the reliability and safety of service were comparable to present-day railroad standard. Merchandise and express will probably be collected in the downtown districts of New York and Chicago between 6 and 7 P. M., with delivery the following morning in the opposite city between 7 and 8 o'clock. It will be necessary to charge probably between $1 and $2 a pound, at least during the development period. To assure absolute reliability will require a very thorough organization of ground, navigational beacons and landing fields, for which it may be possible to gain generous Government support, if it can be demonstrated that the service contemplated will fill a sufficiently important business demand.

"Your association is in a position to render a valuable service to this office if you will undertake to determine what the probable volume of business will be which will patronize an air transportation service such as outlined at the rates suggested. It is the desire of the Government to encourage these activities in civil aeronautics which will most directly bring about the creation of a self-supporting aeronautical industry and the co-operation of your association to that end will be appreciated."

The association, in commending the request to the consideration of its members, asks a statement from them of their views as to the utility of the proposed service, together with an estimate of the quantity of traffic which each one probably will be able to supply to the support of the line. The data will be transmitted to the War Department in accordance with the request of Major General Patrick. While it may not be possible, the association adds, for every member to estimate accurately the extent of the traffic which he could supply, it is nevertheless probable that many merchants could make an approximate estimate of the extent to which they could use the proposed transportation agency, and urges that this be done.

Fokker in America

A. H. G. Fokker, Dutch aeroplane manufacturer, reached port May 28 on the Holland America liner Nieuw Amsterdam, bringing with him two new planes which will be used in this country.

Mr. Fokker said that it would soon be as safe or safer to travel in aeroplanes than in street cars. Every one in Europe now is using planes as they use automobiles, and the companies operating aeroplanes have had to establish waiting lists.

The inventor is here for a visit of two months to look into the use of his planes in this country.

Greater Safety for Air Travellers

Pending the enactment of legislation for the regulation of air navigation the National Advisory Committee for Aeronautics in a resolution adopted recently calls upon the operators of aircraft to voluntarily equip their aircraft to promote the safety and comfort of passengers. It is the Committee's opinion that the suffering and loss of life attending forced landings of aircraft on land or water can in all probability be lessened by making use of existing knowledge and facilities. To this end the Committee urges "that large seaplanes should be provided with wireless and other signaling equipment, be seaworthy as well as airworthy, and carry at all times fire extinguishers, life preservers, a first-aid kit, and a supply of food and fresh water; that aeroplanes operating over the land should carry wireless or other signaling apparatus, fire extinguishers, and a first-aid kit." It is understood that the accident to "Miss Miami" in which four persons lost their lives, for want of reasonable precautions to provide for the safety of air travellers, prompted this action by the National Advisory Committee for Aeronautics. Legislation for the regulation of air navigation is now pending in Congress. A bill introduced by Senator Wadsworth to create a Bureau of Civil Aeronautics in the Department of Commerce has already passed the Senate.

Round the World Flight Starts

LONDON—Major W. T. Blake, Captain Norman MacMillan and Lieut. Col. Broome started May 24 from the Croydon aerodrome in an attempt to fly around the world. They are using a DH19 aeroplane, and hope to complete the journey in about ninety days, reaching Croydon on Sept. 7. Their route as planned is 30,000 miles long.

Major Gen. Sir William Brancker, Director General of Civil Aviation, attended to wish them good luck, and a message from the King and Queen was handed to Major Blake as he stepped aboard the aeroplane: "Their Majesties wish you all godspeed and good luck."

Major Blake's wife and little daughter Barbara, as well as his father and mother, came to see the starting. His wife handed him a black cat mascot as she kissed him good-bye.

Enthusiastic cheers were raised by a large crowd of well-wishers as the aeroplane left the ground.

Navy Launches Fighting Planes With Passengers From Ship Deck

The Navy Department announced the successful experiment of launching the service type of seaplanes from the decks of vessels by use of the catapult. The planes are powerful enough for both observation and fighting purposes.

The experiment was made from the deck of the battleship Maryland, the country's most powerful sea fighter, at Yorktown, Va., on May 24.

This is the first time it has been possible to launch an effective plane carrying passengers and well weighted. Heretofore the experiments have been with small and unserviceable planes without loads.

The success of the experiment is regarded by navy officials as the means of meeting the menace to battleship by attack from the air and is the defensive reply to the air offensive demonstrated in the recent bombing experiments of the army and navy.

It is interpreted by the experts as meaning that the battleship remains the fighting unit of the navy, which aims to equip every battleship with the mechanism necessary for launching a fighting airship while at sea.

The project of catapulting planes from a ship was effected first in 1915 on board the North Carolina, followed in 1916 by further experiments on the Huntington.

Flight of 1,000 Miles at 110 Miles an Hour

Washington.—Major Roy C. Geiger of the Marine Corps is believed to have broken the record for time and long-distance North and South flying May 27 between Quantico, Virginia and Pensacola, Florida, in a D. H. D.-4 Marine Corps type plane with a Liberty motor.

Major Geiger left Quantico, thirty miles south of Washington, at 4:40 A. M. and arrived at Pensacola at 3:30 in the afternoon. This time included approximately two hours of stop-over, making the actual flying time less than nine hours. The trip was made at an average speed of about 110 miles an hour over a distance estimated at 1,000 miles.

Two stops were made, the first at the Army Aviation Field at Fayetteville, N. C., for an hour and a half. During that time the plane and motor were inspected and oil, gas and water obtained. The second stop was at Americus, Georgia, for about half an hour while the tanks of the machine were being recharged with gas. Major Geiger carried Sergeant John Belcher with him on the trip and about fifty pounds of baggage.

Experts at Marine Corps aviation headquarters said that Major Geiger's time was undoubtedly the fastest ever accomplished between Quantico and Pensacola, where the country to be covered is broken and difficult to negotiate. They said the speed for the journey was phenomenal and they believe that Major Geiger may have broken the world's record for speed over that distance.

The AIRCRAFT TRADE REVIEW

Huff Daland Aeroplanes at McCook Field

A great deal of interest has been aroused at McCook Field in the two types of Huff, Daland and Company's thick wing biplanes now under test by the Engineering Section of the Air Service.

This company has been specializing in the manufacture of very simply constructed aircraft which use the Gottingen 387 thick wing and are remarkable for the liberal use of plywood and steel tubing in their structure. At present there are two types of planes at McCook.

The first type, which has already been flown and is now undergoing its official performance tests, is the OX5 motored two or three place, officially known as the HD8A, which this company is marketing under the trade name of PETREL. This plane is a development of the Anzani motored machine with the same wings which was flown by Lieutenant Harris last Fall. Its makers claim a top speed of ninety-three miles per hour and a landing speed of less than thirty five with a total useful load of seven hundred and thirty six pounds. Insomuch as the entire surface of the plane is less than two hundred at thirty square feet, this performance is considered very remarkable.

The PETREL has been very thoroughly tested as regards its structure. Its radiator has been flow tested. Its propeller has undergone an endurance test at 1800 RPM. Its struts have been pulled in an Olsen machine, and aside from a few minor changes, the plane has been approved as manufactured. This plane is now undergoing its performance tests, and figures will be issued shortly. Up to the present no attempt has been made to check the figures which resulted from the manufacturer's tests at Ogdensburg, but Captain McCready reports that the PETREL as flown last week is very easy to control, which is one of the manufacturer's chief claims.

The second type of plane which this company is manufacturing for the Air Service specifications, is a smaller version of the PETREL, with 176 square feet of surface and the 140 HP Model R nine cylinder Lawrence motor. The plane has the Gottingen wing, but unlike the PETREL its wing is tapered upward in thickness and forward from the center of the trailing edge in chord for greater speed. The ship is designed as a pursuit training plane and is claimed to have all the flying characteristics of a single seater service machine, together with a low landing speed and high safety factor. In appearance it shows much thought in its perfect stream-lining, large angle of attack when landing, and general clean appearance. In regard to surface and loading it is similar to the fifteen square meter Neuport which was considered the most maneouverable aeroplane of its class by pilot's who went through the French pursuit schools overseas. However, it should be remembered that this plane is powered with 140 HP.

Huff Daland and Company claim for their Lawrence plane a high speed in excess of 120 MPH, in addition to its maneouverability and low landing speed, so that the official tests on this two seater will be of utmost interest.

The results of the performance tests on both these planes will be published in these columns as soon as such publication is authorized.

Curtiss Oriole for Capt. Roald Amundsen's North Pole Expedition

ONE of the most important pieces of equipment which left Seattle with Capt. Roald Amundsen's North Pole expedition on the three-masted schooner "Maud" is a stock Curtiss "Oriole" with a Curtiss C-6, 160 h.p. motor, equipped with electric starter. This plane was presented to Capt. Amundsen by the Curtiss Aeroplane and Motor Corporation and christened at the Curtiss Flying Field, Garden Ctiy, L. I., on April 6, 1922, and now bears the name "Kristine." The fact that Capt. Amundsen has equipped his expedition with a modern aeroplane shows that he appreciates the advantages to be gained by this means of transportation. It is his plan to drift across the Polar Basin in the vicinity of the North Pole with the Schooner "Maud" and during the passage make exploring and mapping trips in all directions radiating from the supply ship, using the ship as a base. By doing this it will be possible to cover a vastly greater area of country and to secure photographs from which can be produced an accurate map of the country giving both the geography of the territory and the general condition of the terrain.

Capt. Amundsen has secured as his pilot Lt. Oskar Omdal, formerly of the Norwegian Navy. Lt. Omdal has selected a specially qualified crew to keep the plane in condition to operate under the severe weather conditions which they expect to encounter. The "Oriole" has been equipped with snow skids which are interchangeable with the landing wheels and tail skid. Additional gasoline tanks have been installed making the total fuel capacity ninety-four gallons of gasoline, or sufficient fuel at cruising speed to cover a distance of six hundred and forty miles. An aeroplane to operate under the varying weather conditions which will be met on this expedition must be equipped with special devices for regulating the temperature of the motor, of the cooling water and of the lubricating oil, and in this case the Curtiss company have gone a step further and equipped this plane with a Reed duralumin propeller to withstand varying temperatures and moisture conditions and in case of a bad landing it may be possible to salvage a propeller of this kind, where with a wooden propeller the crew would be hopelessly stranded. A detailed summary of the "Oriole" is as follows:

Weight of machine empty (with wheels) 1788 lbs. (with skids)	1845 lbs.
Oil, 5 gal.	37 "
Gasoline, 94 gal.	564 "
Water, 6.6 gal.	55 "
Pilot	160 "
Passenger	166 "
Weight with full load	2770 lbs.
Loading: Area	399.7 sq. ft.
Lbs. per sq. ft.	6.93
Lbs. per h.p.	17.29
High Speed	96 m.p.h.
Low Speed	45 m.p.h.

One of the objects in the presentation by the Curtiss Aeroplane and Motor Corporation of this ship to Capt. Amundsen was the desire to learn something of the operation of the C-6 in the "Oriole" under the severe atmospheric conditions which will be encountered in the Arctic, and further desire to have the Reed metal propeller, which was invented by Mr. S. A. Reed, and of which a number have been built under his direction at the Curtiss factory, tried out under the atmospheric conditions which a metal propeller is supposed to be particularly adapted to withstand. Capt. Amundsen is keeping the Curtiss Aeroplane and Motor Corporation fully advised of the operation of this ship and motor, and is planning if possible to return the ship and motor to the Curtis Company at the end of his expedition with a full report of the details of their operation.

COMMERCIAL AVIATION DEVELOPMENT IN THE UNITED STATES

By W. KNIGHT, M. E.

IN A SERIES of articles published in the AERIAL AGE of March 20th and 27th, and April 10th and 17th, 1922, I have summarized the developments of commercial aviation in Europe up to the end of 1921 and I have tried to show that, in spite of the fact that some very decided progress has been made in the organization of aerial transports in Europe in the last three years, they are far as yet from being a success, both from the point of view of the public and the investor in aerial securities.

In every country in Europe commercial aviation activities were born under the regime of a paternalistic government protectorate and have been able to survive and to further expand (in spite of the fact that every one of them represents a dead loss of money), due to the substantial subsidies which have been most generously lavished upon them by the various governments. The French government has contributed more than any other government in Europe to the development of both its military and commercial aeronautical activities, and France is today in a position to claim the supremacy of the air in Europe.

After almost three years of operation and expansion of aerial transports in France and elsewhere under these conditions, a point has now been reached when the people in Europe, and especially in France, begin to wonder what is the matter with commercial aviation which after three years of operation under the regime of government subsidies is unable to earn as yet one-quarter of its operating expenses.

Government subsidies and government control offer some advantages but they also offer a good many disadvantages. Government control of business activities and government subsidies intended to make good the losses incurred in the development of a new national industry and in opening up new international commercial lines of communication are very desirable in some cases as an emergency measure, but in the end they are bound to be detrimental to the development of any commercial enterprise on a healthy business basis if the practice of substituting governmental paternalism to unhampered business initiative is not stopped in time.

Government officials in every country, by necessity of their training in the government service whose business is to raise and to spend the money contributed by taxpayers, are not always particularly competent when it comes to the point of making money out of a business controlled by the government. The history of the business adventures of the government of the United States during the war and after the war is a recent instance that we all know of.

The injection of politics, government control and subsidies into any business activity for any extended period of time is bound to destroy business efficiency in the end and this is what both the people and the governments in Europe are beginning to realize, in so far as commercial aeronautical developments are concerned.

In the United States we have not had up to the present time any government intervention under the form of subsidies for establishing aerial commercial lines in this country, in spite of the fact that the Air Mail Service established and run by the Post Office Department of the U. S. Government stands so far as the biggest and the best organized undertaking of commercial aviation in the world. It is most likely that we shall never have any subsidies paid to our aerial transportation company under the same form as they are paid in Europe, except for whatever service they might be able to perform for the government—as, for instance, for transporting mail at a certain rate per ton-mile with a guaranty of a minimum load for each trip.

The idea of paying subsidies to aerial transport companies as an inducement to them for starting and developing commercial aviation in the United States and to reimburse the losses incurred by them in the operation of aerial lines is undemocratic and against the fundamental American business canons. If the people in this country want this kind of service they can have it, but it is up to them to organize aerial transport companies and to run them as any other business activity with as little interference on the part of the government as is possible and desirable in an undertaking of this nature, which is bound to have a tremendously important bearing on our national defence and on the development of our foreign trade.

Due to the lack of government subsidies and to the fact that right after the war the aircraft manufacturing industry both in this country and abroad had not developed as yet a type of motor and airplane well adapted to commercial exploitation, our business men have been slow in starting any commercial aviation activities in this country. During the last two years, however, some very decided progress has been made by the aircraft manufacturing industry both in Europe and in the United States. Better motors and better airplanes have made their appearance. Metallic airplanes (which are the logical aerial carriers of the future) have been developed, and the airplane has ceased to be a war engine and is now well on the road to become a means of transportation as safe, practical and economical, under reasonable limitations, as any other,—and a good deal more rapid and flexible than any other present means of transportation.

During the last two years, however, in spite of the lack of government subsidies and in spite of the lack of regularly operating aerial lines and of clearly defined national policy and program in aeronautics in this country, almost 31,000,000 miles were flown by both military and civilian aircraft, and 500,000 passengers were carried by civilian airplanes, in addition to many tons of freight.

The failure of Congress to enact a much needed aerial legislation making possible easier credits and more satisfactory insurance rates has been greatly responsible for retarding so far the establishment of regular commercial aerial lines in the United States, which is better adapted than any other country in Europe (with the exception of Russia, possibly) to this new means of transportation of freight and passengers. The action of some incompetent self-styled business men, with no knowledge at all of commercial aviation problems, in starting an aerial transport corporation with great plans for tieing together all the most important commercial centers in the United States and finally failing in the most inglorious way for lack of elementary business sense and common honesty, has also contributed in discouraging people here from investing their money in aerial securities.

The failure of aircraft manufacturers, who are more interested than anybody else in the establishment and development of aerial transportation companies in America, in taking the initiative in opening up and keeping in operation one or two regular aeral lines, just as aircraft manufacturers in Europe did right after the war and are still doing at the present time, has not contributed a bit in inspiring confidence in the public in a means of transportation in which apparently aircraft manufacturers had not enough confidence to invest their money in, all the time, however, keeping the prices of their products sufficiently high to pay for the expense of their partially inactive manufacturing establishments and putting up a lively fight for preventing the dumping into this country of cheaper foreign aircrafts.

The lack of proper financial support that our Aero-Club, the Aeronautical Chamber of Commerce and similar organizations are receiving from the public, the government and aircraft manufacturers is another contributing cause of our slow progress in commercial aviation developments. This, in spite of the fact that both the Aero-Club and the Aeronautical Chamber of Commerce are two organizations which by working together harmoniously and intelligently can render valuable service to our aircraft manufacturing industry and can greatly contribute in eliciting the interest of the public both in this country and abroad in our aeronautical activities. This fact is well recognized in France, where the Aero-Club is one of the best organized in Europe, is a force to be reckoned with in any aeronautical event taking place on the European continent, and is doing a splendid work for contributing to the development of commercial aviation in the world and for protecting and advertising all over the world French aeronautical interests.

In spite, however, of all limitations and handicaps; in spite of the lack of a much needed legislation on aeronautics; in spite of crooks who have tried to use aeronautics as a swindling proposition; the advent of commercial aviation in the United States is coming, is coming fast and once we get started there will be nothing to stop us, and inside of a few years we shall probably lead the world in commercial aviation developments.

We are far behind Europe at the present time because we did not believe, and we do not believe, in government subsidies and government control of aerial operating companies. We do believe, however, that the government, in cooperation with business and technical men and organizations interested in aeronautics, must provide us with aeronautical laws and regula-

Digitized by Google

tions, landing fields, meteorological and wireless services, just as European governments are doing. We believe that the government must protect and encourage by any means the development of our aircraft manufacturing industry but, at the same time, aerial operating companies, if they are not expected to operate aerial lines at a loss, especially during the first year or two of operation, cannot be required to buy aircrafts in America if American aircraft manufacturers cannot supply as good aeroplanes as are obtainable in Europe, at such a price as to make it possible for the operating companies to consider the patriotic end of the transaction when they must decide whether to buy their equipment in the United States or in Europe.

To be patriotic about the development of a national aircraft manufacturing industry is all right, of course, but aircraft manufacturers in this country, who have made very substantial profits during the war, must keep in mind that patriotic considerations and business considerations cannot always prevail at the same time unless they are well balanced together. We shall be able to buy good commercial aircrafts in the United States for operating our aerial lines, and we shall be able to afford paying more for them than we would pay for equally good aircrafts made in Europe, provided, however, that our aircraft manufacturers are prepared to buy stock in the operating companies and to share with them the risks and the benefits of the operation of our commercial lines during the first years of operation, if it is so desired. If not, I do not see why our aerial operating companies should not go and buy their flying equipment in England, France, Germany or Italy, wherever they can secure the best terms, unless our aircraft manufacturers can meet the competition of foreign manufacturers in the matter of prices and quality, which they cannot do.

We did not want commercial aviation to be born in this country under the regime of government subsidies and government control because the experience that we have had with such things since the late war has brought us to the conclusion that what we want is: more businesslike methods in our government and less (a good deal less) government control over our business enterprises. However, what we want now is that a real constructive work be started without any further delay for putting on the map of the world commercial aviation in the United tSates, and we want everybody directly interested in this matter to take a share of the responsibilities involved in such an undertaking.

Let Congress take its own share of responsibility and act on the Wadsworth Bill "to create a Bureau of Civil Aeronautics in the Department of Commerce, to encourage and regulate the operation of civil aircraft in interstate and foreign commerce and for other purposes," and on other legislation as affecting civil aviation which has now been under consideration by Congress for quite a long time.

Let the financial groups interested in the development of civil aviation in the United States take a hand in seeing that the proper legislation is suggested to and is enacted by Congress at the earliest possible date. Financiers interested in civil aviation developments should also try to discourage at the present time the establishment of a number of small aerial companies. It is much preferable at the present stage of the game to concentrate all efforts into trying to build up and to gradually expand one financially strong company, rather than financing with small means a dozen companies. We must keep in mind that the progress of civil aviation at the beginning is to be obtained through cooperation and not through competition, and that the large overhead expenses of small European companies are largely responsible for the deficit of their budgets.

Promoters of aerial companies must remember that the troubles of European companies in Europe are due to three main reasons: First, aeroplanes not well adapted to commercial exploitation; second, imperfect organization of ground services; and third, insufficient commercial loads. Commercial aeroplanes which it is anticipated will be scrapped after 1000 hours' flight or less and motors requiring overhauling after 100 to 200 hours of operation are too heavy a burden on the operating expenses. An imperfect ground organization is responsible for most of the accidents taking place, is responsible to a large extent for the prevailing high insurance rates, and adds considerably to the operating expenses. Aeroplanes traveling always half loaded are not a paying proposition.

The trouble with the aerial lines in Europe so far has been that they have relied too much on the transportation of passengers and that they have not gone strongly enough after the merchandise transportation business. We should start with mail, express matter and freight. After we have succeeded in convincing people that aeroplanes can be operated safely and regularly on scheduled time all year around, when the farmers in the fields shall regulate their watches every day when the 12:15 or the 2:45 aerial express flies above, then we shall know that we can rely on having all the passengers that we want.

The air line between New York and Chicago most likely shall be the first trunk line to be open to traffic, and the operation of this line will spell the success or the postponement of commercial aviation developments in this country. However, we must keep in mind that one trunk line only, even if that be the New York-Chicago, connecting two of the most important commercial centers in the country, cannot attract at the beginning enough traffic to pay for further expansions and that, rather than encouraging the establishment of other companies for operating other trunk lines in connection with the New York-Chicago, we shall have to try to build up and to gradually expand our activities around one main company and make it a strong foundation of our future civil aviation developments thus keeping down overhead expenses and securing a much needed singleness of policy.

Aircraft manufacturers, as I said before, must be prepared to take quite an active interest in the establishment and the development of aerial operating companies and must not look forward to immediate profits while doing business with new operating companies; on the contrary, they must be prepared to help them along with good flying equipment, low prices and long credits if they are interested in getting the business and in defeating the competition of foreign aircraft manufacturers. Commercial aviation is not going to be a booming business for aircraft manufacturers for the first year or two, and they must be prepared to take their share of responsibility in such an undertaking, from which they are bound to gather handsome profits after the aerial operating companies have been successful in operating aeroplanes manufactured by them.

From the Aeronautical Chamber of Commerce, the Aero-Club and all other similar organizations created for the purpose of encouraging the development of commercial aviation in this country and in the world, I think that it is fair to expect fewer programs of future activities and more reports of results obtained. As I mentioned before, however, these organizatioos cannot be expected to operate without sufficient financial means at their disposal and this financial support must be supplied by the government (city, state and federal), by aircraft manufacturers, aerial operating companies, commercial and financial groups interested in civil aviation developments.

The Aeronautical Chamber of Commerce and the Aero-Club can contribute to the development of commercial aviation in this country and to the expansion of our activities abroad more than any other organization, if we allow them to become the national and international organs of propaganda of our aeronautical activities and the official sponsors of inter-state and national legislation needed in this country for regulating the traffic in the air, and for securing the cooperation of districts and localities in providing properly equipped air harbors and intermediary air lanes under unified federal control.

The extension of the activities abroad of both the Aeronautical Chamber of Commerce and the Aero-Club, in establishing and maintaining a cordial exchange of information and data on commercial aviation developments between aeronautical interests in this country and in Europe and in establishing an effective cooperation between ourselves and Europe in the solution of the international problems which we are bound to face as we develop our activities in the air, is another valuable service which these two organizations can render us.

Three years ago I suggested the extension abroad of the activities of the National Advisory Committee for Aeronautics, for the purpose of establishing an exchange of information and technical data on aeronautics and sciences thereto allied between the U. S. government, on the one hand, and government organizations, technical men, and private concerns in Europe on the other hand. I made this suggestion for the purpose of preserving and further developing the fine spirit of cooperation in the solution of technical problems in aeronautics which prevailed among the allied and associate nations during the war and which was going to be discontinued at the end of the war. My suggestion was taken up by the National Advisory Committee for Aeronautics and I had a chance to realize my project of intellectual international cooperation between ourselves and European government officials of former allied, associated, and former enemy nations, and scientists and technical men in the United States and in Europe interested in technical aeronautical developments. I was appointed Technical Assistant in Europe to the National Advisory Committee for Aeronautics, and from May, 1919, to May, 1921, while acting in the above named capacity, I had the opportunity of creating an effective liaison service between our National Advisory Committee for Aeronautics and technical aeronautical organizations in England, France, Italy, Belgium, Germany, Austria and Holland, whereby our government has been kept fully informed of any progress made in aeronautics as a science and as a branch of engineering. The main and, in my estimation, the most important contribution which has been made by the National Advisory Committee for Aeronautics to the development of aeronautics through the establishment of an office in Europe, has been the promoting of a fine spirit of cordial cooperation between scientists and

Digitized by Google

technical men interested in scientific and technical research work in aeronautics.

This fine spirit of coöperation which can be brought about only through personal contact and which can be based only on the reciprocity of advantages to be derived from the exchange of most confidential data and information and the interchange of views on the various aspects of problems under consideration, is a very desirable spirit which, by every means, must be promoted and developed between manufacturing, commercial and financial aeronautical interests in this country and in Europe. In other words, the same exchange of information, the same direct contact which has been established and developed by the National Advisory Committee for Aeronautics and scientists and technical men in Europe, should be established and developed between aircraft manufacturers, aerial operating companies and financial groups interested in commercial aviation developments, both in this country and in Europe.

This work cannot be undertaken by the government through the accredited diplomatic or consular channels. Aeronautical attachés, commercial attachés, consular agents and other government officials in foreign service are necessarily limited in their actions, which must be governed by general rules and regulations in order to prevent interferance between the various agencies of the government working on the same job; and such rules and regulations as are inspired by general governmental policies are not and cannot always be efficient from a limited and well-defined business point of view and in some cases they work exactly the opposite way.

For instance, my personal experience during the two years that I was the representative in Europe of the National Advisory Committee for Aeronautics was that while I was trying to establish a personal and direct contact between individuals and organizations in Europe and in the United States interested in aeronautical developments (which is the only way to exchange valuable information) I was always interfering with the work of naval and military aeronautical attachés who were trying to obtain information on the same subject through regular diplomatic channels. It is quite obvious that individual and private concerns which are ready to cooperate with other individuals and private concerns in a foreign country, with a view of eventually developing their cooperation into a tangible form of business cooperation, do not care a snap about an impersonal inter-governmental exchange of data and information. Considering the fact that I was obtaining most satisfactory results along the line of cooperation which I had suggested, and that I was securing for the National Advisory Committee for Aeronautics through the establishment of personal contacts more complete data and information than it was possible to obtain through other channels, from a point of view of business efficiency, such a work should have been encouraged and further developed. However, the Committee being as it is a governmental organization, the work of its European office had to be brought in line with the work of other similar agencies of the U. S. government foreign service. This was the only proper thing to do and although I knew that such a step would curtail the efficiency of my office I suggested that the Paris office of the National Advisory Committee for Aeronautics be put under the direct control of the various embassies in Europe, which was eventually done.

I said before that what we need at the present time is more business in the government and less government in our business. This is true of aeronautics as well as of any other branch of activity and applies both to this country and to other countries. In so far as our contacts with aeronautical developments in Europe are concerned, it seems to me that it would be to the advantage of everybody concerned if direct contacts were established on a basis of mutual cooperation in exchanging data and information between aeronautical interests in this country and in Europe, without relying on government organizations to do it for us. Of course, so far, we have not had any commercial aerial operating company in this country, and all it was possible to do was what the government has done for collecting statistical and other data about commercial aviation developments in Europe, which will be of great assistance to us in avoiding making the same errors that were made in Europe during the last three years. Considering, however, that we are on the eve of important developments in civil aviation in the United States, it seems to me that we should take into proper account, right at the beginning, the international aspect of this new means of transportation, and this is bound to have quite a tremendous bearing on its development.

The international aspect of aviation is so wrapped up with its national aspect in Europe that from every quarter, even from those more inclined to follow a strictly national aeronautical policy, the need of agreements and cooperation with foreign operating companies is freely advocated in the aeronautical press by aeronautical interests. The necessity of freeing commercial aviation from the bonds imposed upon it by political considerations under the prevailing regime of government tutelage, brought about by the unbusinesslike method of paying subsidies to operating companies to make up for the losses incurred in the operation of aerial lines, is felt every day more keenly and the necessity of establishing direct contacts with foreign aerial operating companies becomes every day more evident from the point of view of business efficiency.

At the present time we are not much concerned with international civil aviation, as we have enough problems of our own to solve in order to put American aviation on the map of the United States. But on the other hand we all realize that inside of a very few years the Atlantic and Pacific oceans will be crossed quite regularly by airships as well as by steamships, and that in a much nearer future we will fly every day to Canada, Mexico, Cuba and South America. And even at the present time when direct shipments can be made right through from Moscow to Havre, or even to Casablanca, I do not see why we should not make arrangements with European aerial operating companies and steamship companies which will allow the making of direct shipments from Moscow to Chicago or San Francisco.

A number of problems are connected with the international side of commercial aviation which are purely business points, and they must be handled through business channels. Close contacts between American and European aeronautical interests in a spirit of mutual cooperation in the solution of common problems is what we need to inaugurate right at the outset of our aeronautical activities in the United States. For this reason we must anticipate the organization of an international association of aerial transportation companies and an international aeronautical Chamber of Commerce, the first one grouping together the most important aerial transportation companies in Europe and in America and the second one coordinating the work of the various aeronautical Chambers of Commerce, aero clubs and similar organizations throughout the world.

The International Air Traffic Association (I. A. T. A.), organized in 1919 by M. Holt Thomas of the "Airco," would admirably serve the purpose for which it was created (which is somewhat similar to the one that we are advocating) if the most important aerial operating companies in Europe had taken an active interest in such an organization. As it is at present, the I. A. T. A. is only an international organism possessing great potential possibilities of an effective cooperation between aerial operating companies which, however, are not sufficiently made use of or sufficiently extended as they should be. In order to obtain an immediate constructive participation of the most important aerial companies in the membership of the I. A. T. A. or of any other similar international association of business concerns in matters of common interest, I think that it would be a good plan to start a move whereby an exchange of capital stock between these companies might take place. If each of the most important aerial operating companies should become a minority stockholder in all equally important foreign aerial operating companies, cooperation between them and a common participation in the solution of international commercial problems would become part of a policy based on limited partnership with each other, this being something which is understood by every business concern and a good deal more efficient than the more or less sentimental general resolutions which are usually adopted at the end of each international aeronautical Congress, without being followed by any immediate practical results. Business concerns are not inclined to waste time and money in international debating associations. They are accustomed to dealing with balance sheets and cold facts. The best ties to unite the most important aerial operating companies in the world are those which are established at the meetings of the board of directors of each of them, where the other companies are represented as minority stockholders.

For the same reasons, the best cooperation between operating companies and aircraft manufacturers is obtained by having the leading aircraft manufacturers in each country become minority stockholders in national aerial operating companies. In this way, the cooperation between operating and maufacturing interests in each country is based on a business partnership between operating companies and manufacturers, the operating companies, however, always reserving the control of the transportation business. In the same way, while the international cooperation between operating companies, under such a plan, would be based on the same principle of partnership with foreign operating companies, each company would always have to retain control of its business.

The international association of aerial transportation companies mentioned above should simply be the organ of coordination of the interests of the various companies in its membership and to that body would be assigned the work of making investigations, preparing reports and suggesting actions and agreements in the interest of the various companies, besides being the official international organ sanctioning any agreement between its member companies.

The International Aeronautical Chamber of Commerce, it was suggested by Mr. E. Pierrot in France, could be con-

AIR MAIL SERVICE SCHEDULE

C. F. EGGE, general superintendent of the Air Mail Service, has just issued a memorandum showing the mileage between all air mail stations, the maximum number of pounds which may be transported, the origin and kind of mail carried, and the time advanced over rail dispatch.

If the maximum amount of mail is available at each station, the Air Mail advances the delivery of 6,250 pounds or, at forty letters per pound, a total of 250,000 letters daily.

Since July 1, 1921, the percentage of performance has been better than ninety-four, which means that out of each hundred trips scheduled ninety-four were completed.

Air Mail Service Schedule

New York to San Francisco
(Daily except Sundays and Holidays)
Effective May 15, 1922

WEST

Miles

Leave New York 6:00 a. m.,
Arrive Bellefonte 8:55 a. m..... 225
Leave Bellefonte 9:15 a. m.,
Arrive Cleveland by 12 noon.... 210

500 pounds. All letter mail for Cleveland accumulated in New York Postal zone after 8:40 p. m., leaving time of New York and Chicago R. P. O. Train 35. Letter mail for Bellefonte accumulated after midnight. Balance load will be Chicago gateway mail held off New York and Chicago R. P. O. Train 9 due to leave New York 5:15 a. m. (due arrive Cleveland 10:50 p. m) for dispatch to New York and Chicago R. P. O. Train 35 due Cleveland 12:35 p. m. At Bellefonte take on pouch for Cleveland to contain mail for that office and connections. (All Cleveland mail advanced one business day. Air mail arrives before noon; by rail would arrive 5:30 p. m. Train 9 due Chicago 8:00, therefore Chicago gateway mail delivered twenty hours earlier than by rail.)

Miles

Leave Cleveland 8:40 a. m. (E. T.),
Arrive Bryan 9:40 a. m. (C. T.) 160
Leave Bryan 10:00 a. m.,
Arrive Chicago by 12:15 p. m... 175

500 pounds. Take Chicago city mail off New York and Chicago R. P. O. Train 19 due to arrive Cleveland 8:00 a. m. Cleveland office will dispatch pouch for Chicago and Bryan. Bryan will dispatch to Chicago. (Chicago mail advanced one business day in delivery. Train 19 due to arrive Chicago too late for delivery by carrier that day. Chicago mail received at Cleveland has been worked for carrier and station distribution by railway postal clerks in Train 19 between New York and Cleveland. One day service between New York and Chicago. Mail leaving New York 5:30 p. m. delivered by carriers following day in Chicago.)

Miles

Leave Chicago 6:00 a. m.,
Arrive Iowa City 8:00 a. m...... 195
Leave Iowa City 8:20 a. m.,
Arrive Omaha by 11:30 a. m.... 230

500 pounds. 250 pounds Omaha city and balance California and western mail to connect Omaha and Ogden R. P. O. Train 5 at North Platte. (Omaha city mail worked in terminal R. P. O. in Chicago for carrier and station distribution. Delivery advanced one business day.)

Miles

Leave Omaha 1:00 p. m.,
Arrive North Platte 4:15 p. m. (C. T. 245

(Do not hold later than 1:30 p. m. for ship from Chicago, or Omaha train connections.)

500 pounds. Take western mail from Chicago ship, one pouch each for North Platte and Train 5 from Omaha and 300 pounds western mail from C. B. & K. C. Train 27, Minneapolis & Sioux City Train 11-9 and Aberdeen & Sioux City Train 4-104 received at Omaha from Huron & Omaha C. P. Train 209 for dispatch to Train 5 due to leave North Platte 4:32 p. m. (Train 5 is exclusive mail train on fast schedule. All mail handled Omaha to North Platte by air advanced one business day.)

Miles

Leave North Platte 7:30 a. m. (M. T.),
Arrive Cheyenne 10:15 a. m..... 215
Leave Cheyenne 10:35 a. m.,
Arrive Rawlins 12:30 p. m...... 134
Leave Rawlins 12:50 p. m.,
Arrive Rock Springs by 2:15 p.m. 106

500 pounds. Take mail for Cheyenne, Rawlins, Rock Springs, Billings & Denver Trains 31 and 32 via Cheyenne, and Omaha & Ogden Train 3 via Cheyenne, from Omaha & Ogden R. P. O. Train 13 due to arrive North Platte 7:10 a. m. At Cheyenne take on all mail available, which includes Cheyenne pouch for Rock Springs and pouches for Rawlins and Rock Springs from Train 13 received via plane from North Platte. (Train 13 due arrive Cheyenne 3:10 p. m., Rawlins 8:10 p. m. and Rock Springs 12:11 a. m. All mail flown from North Platte advanced one business day.)

Miles

Leave Rock Springs 6:30 a. m.,
Arrive Salt Lake by 8:15 a. m. (M. T.) 155

400 pounds. Take Salt Lake City letter mail off Omaha & Ogden R. P. O. Train 5 due arrive Rock Springs 4:36 a. m. (Delivery advanced Salt Lake City one business day. Train 5 arrives Salt Lake too late for delivery by carrier that day. Salt Lake City mail received from Train 5 has been worked for carrier and station distribution by postal clerks in Train 5.)

Miles

Leave Salt Lake City 6:30 a.m. (W.T.)
Arrive Elko 8:45 a. m.......... 205
Leave Elko 9:00 a. m.,
Arrive Reno 12 noon............ 235
Leave Reno 12:15 p. m.,
Arrive San Francisco by 2:15 p. m. 190

400 pounds. Take letter mail for Elko, Reno and San Francisco accumulated at Ogden and Salt Lake after departure of Ogden & San Francisco R. P. O. Train 9, leaving 12:55 p. m. Elko will dispatch pouches for Reno and San Francisco. Reno will pouch on San Francisco. (Mail delivered in San Francisco eighteen hours and fifteen minutes earlier than arrival by rail.)

EAST

Miles

Leave San Francisco 2:30 p.m. (W.T.)
Arrive Reno by 4:30 p. m....... 190

400 pounds. Take all eastern mail accumulated at San Francisco after departure of Ogden & San Francisco Train 2, due to leave San Francisco 11:00 a. m.; also pouch for Reno. Dispatch eastern mail to Train 2, which is due to depart Reno 9:30 p. m. (Mail for Chicago and east advanced one business day by overtaking fast Train 2 at Reno.)

Miles

Leave Reno 6:30 a. m. (W. T.),
Arrive Elko 9:00 a. m......... 235
Leave Elko 9:15 a. m.,
Arrive Salt Lake by 11:30 a. m., (M. T.) 205

400 pounds. Take eastern mail off Ogden & San Francisco Train 20, due to arrive Reno at 4:35 a. m., and dispatch to Omaha & Ogden Train 2, due to leave Salt Lake 12:00 noon. San Francisco dispatch pouch for Salt Lake via Train 20. Reno pouch on Elko and Salt Lake; Elko pouch on Salt Lake. (Train 20 leaves San Francisco 6:00 p. m. and this dispatch connects at Ogden with Train 2, which left San Francisco at 1:00 a. m. previous day. Advance eastern mail one business day.)

Miles

Leave Salt Lake 6:45 a. m. (M. T.),
Arrive Rock Springs 8:35 a. m.. 155
Leave Rock Springs 8:55 a. m.,
Arrive Cheyenne by 11:00 a. m.. 240

400 pounds. 150 pounds Salt Lake post office and 250 pounds from S. L. C. & Cal. R. P. O. Train 4, due to arrive 6:00 a. m. Salt Lake office and clerks in Train 4 to pouch on Cheyenne office and on Omaha & Ogden R. P. O. Train 20, due to leave Cheyenne 12:40 p. m. Rock Springs pouch on Cheyenne. (Train 20 leaves Salt Lake at 7:50 p. m. By overtaking this train at Cheyenne eastern mail is advanced one business day.)

Miles

Leave Cheyenne 6:00 a. m. (M. T.),
Arrive North Platte 8:00 a. m. (M. T.) 215
Leave North Platte 9:20 a. m. (C. T.),
Arrive Omaha by noon......... 245

500 pounds. Take Omaha city mail off Omaha & Ogden Train 6, due to arrive Cheyenne 1:30 a. m. (arrive Omaha 4:50 p. m.), and from Omaha & Ogden Train 2, due Cheyenne 5:25 a. m. (due Omaha 7:15 p. m.). Cheyenne to pouch on Omaha and Chicago & Council Bluffs Train 8. Train 2 dispatch New York State and New England States for Chicago & Council Bluffs Train 8 connection due to leave U. P. Transfer, Iowa, at 6:30 p. m. At North Platte take on pouch from that office to contain Omaha city and connection. (Omaha mail advanced in delivery one business day. The same is true of all eastern mail carried between Cheyenne and Omaha.)

Miles

Leave Omaha 8:00 a. m.,
Arrive Iowa City 10:30 a. m..... 230
Leave Iowa City 10:50 a. m.,
Arrive Chicago by 1:00 p. m..... 195

500 pounds. Take Chicago city mail from Omaha post office and from Omaha & Ogden Train 4, due 7:00 a. m., and from Omaha & Denver R. P. O. Train 6, due 7:00 a. m., and Omaha & Ogden Train 12, due 7:05 a. m. Omaha post office pouch on Iowa City; Iowa City pouch on Chicago. (Trains from which Chicago mails were taken due to arrive Chicago 8:00 to 10:00 p. m. Chicago mails advanced in delivery one business day.)

Miles

Leave Chicago 1:00 p. m. (C. T.),
Arrive Bryan 3:00 p. m......... 175
Leave Bryan 3:20 p. m.,
Arrive Cleveland by 6:00 p. m. (E. T.) 160

500 pounds. Take New York City mail and mail for points east of Cleveland formerly dispatched to New York and Chicago R. P. O. Train 10 (leaving Chicago 10:30 a. m. and arriving Cleveland 8:30 p. m.) and from Train 26 (leaving Chicago 12:40 p. m. and arriving Cleveland 8:35 p. m.) for dispatch at Cleveland to New York and Chicago R. P. O. Train 4, due to leave

Digitized by Google

6:15 p. m. and arrive New York 8:00 a. m. Chicago post office dispatch pouch for Train 4 and for Bryan and Cleveland offices; Bryan to dispatch pouch for Cleveland. (New York City mail dispatched at Cleveland to train arriving in New York in time for bank clearance.)

	Miles
Leave Cleveland 6:00 a. m. (E. T.),	
Arrive Bellefonte 8:30 a. m.....	210
Leave Bellefonte 8:45 a. m.,	
Arrive New York by 11:30 a. m.	225

500 pounds. Take New York City letter mail off Train 22, New York and Chicago R. P. O. (due to leave Chicago 5:30 p. m. and arrive Cleveland at 2:56 a. m.) Cleveland will pouch on New York; Bellefonte will pouch on New York. (Train 22 due to arrive New York 5:25. The New York City mail received from Train 22 at Cleveland is worked for carrier and station distribution by railway postal clerks between Chicago and Cleveland. One day service between Chicago and New York. Mail leaving Chicago at 5:30 p. m. delivered by carriers following day in New York.)

Note: The time shown in this schedule for arrival and departure at intermediate stations and arrival at terminals only for reference. Ships will leave intermediate stations as early as possible after being serviced. The time of departure from initial points will be strictly adhered to and our records of past performance indicate that arriving time at the several terminals will, under ordinary circumstances, be much earlier than that shown on this schedule, which has been made on a 70 to 90 miles an hour basis.

NOTES ON PROPELLER DESIGN—IV

GENERAL PROCEEDING IN DESIGN

Technical Note National Advisory Committee for Aeronautics

By MAX M. MUNK

Summary

THE choice of tne number of revolutions and of the diameter, the distribution of thrust, and the values of the constants in the aerodynamical equations of the propeller are discussed.

The exact design of a propeller must be preceded by approximate computations, leading to the general layout, which in turn must be followed by an analytical examination of the propeller, obtained under several conditions of flight. In the previous notes of this series I have discussed these three steps, including the determination of the distribution of thrust, at length. It will be useful to summarize the procedure briefly in this note and to discuss some general principles in connection with it. For the design of a propeller is a laborious undertaking, and the analysis of the finished design ought to confirm that it is correct. The analysis is not the proper method for studying the effects of different assumptions for the layout. This can be done more shortly and more successfully by a general discussion.

The number of revolutions of the propeller is, in general, determined by the engine; but the prohlem often remains as to whether reduction gearing is advisable. Now the reduction gear always has a friction loss of 2% at least. What is more serious, it requires a great additional weight of the propeller and gear, it gives rise to increased stresses of the fuselage, and it involves additional complications and possibilities of dead stops. It is expensive, too. These disadvantages cannot exactly be taken into numerical consideration. But it can be safely said, I think, that the reduction gear is inadvisable if the aerodynamical efficiency of the propeller is increased less than 5% by its application. There are designers who prefer even an aerodynamic loss of 10% to a reduction of the number of revolutions by gearing.

The question of the diameter and of the number of revolutions is not exclusively a question of efficiency. There are, of course, upper limits for the velocity of the blade tips. Besides, the design of the propeller is carried out, having in view one particular condition of flight, whereas the propeller is to be used under very variable conditions. It is desirable that (a) the efficiency be fairly high under all conditions and that (b) the absorbed horsepower at the same number of revolutions remain nearly constant. Only if these two requirements are fulfilled at the same time, can the propeller develop the highest thrust horsepower. These two requirements lead now to a limitation of the tip velocity of the propeller hlades. For this tip velocity determines the average velocity of the blade elements and hence the variation of their angles of attack. But it is this angle of attack which has to conform to the variation of the thrust, and hence the variation of the angle of attack determines the lift coefficient. A calculation shows that for constant density of the air the best lift coefficient corresponds to the usual tip velocity, high enough for a favorable ratio C_L/C_D. This appears if one applies the aerodynamical equations for the blade element. Hence the designer has to keep in mind that a change in the tip velocity has a noticeable effect either on the behavior of the propeller over a wide range of conditions or on its efficiency, and that this effect cannot be neutralized by minor changes in the design.

The question is intimately connected with that of the advisability of variable pitch. I have just mentioned the fact that for constant density a satisfactory propeller can be designed having constant pitch. Variable pitch is useful only for great altitudes. But then indeed it can greatly improve the performance of the propeller. The variation of the pitch enables the propeller to conform to an additional variation of the conditions, that is, the variation of the density of air.

Some designers of variable pitch propellers claim that the center of pressure of the blade sections of their propellers does not travel. Whether this be true or not, it has nothing to do with the variability of the pitch. For the travel of the center of pressure is due to the change of the lift coefficient of the blade elements, which always takes place for different conditions of flight, because the lift coefficient is nearly proportional to the thrust, and the thrust changes. Hence the center of pressure does not travel if the blade section used is one without travel of center of pressure, whether the pitch be changeable or not.

Proceeding now to the general layout, I have shown that the diameter must satisfy the condition:

$$(1)\qquad D < \sqrt[3]{\frac{T}{nV\frac{\rho}{2}}\, C_L/C_D\, \frac{6}{\pi^2}}$$

where T denotes the thrust,
ρ the density of air,
C_L/C_D the lift/drag ratio of the blade section.

This equation gives too high a value for a small velocity of flight such as occurs during the start, for instance. C_L/C_D can be assumed to be 22. The diameter thus obtained is only a rough indication of the upper limit; the weight, the stresses and the structural point of view are not yet taken into account. In general the diameter is given by other considerations, and the following method is valid for any diameter, however determined.

After having made the decision as to the magnitude of the diameter, the required horsepower is to be estimated and to be compared with the horsepower delivered by the engine. The thrust horsepower may be written $N_o = T\,V$. The sum of the thrust horsepower and slip stream loss is then

$$\frac{N_o\,(1 + \sqrt{1 + C_p})}{2} \quad \text{where } C_p = \frac{}{D^2 \frac{\pi}{4} V^2 \frac{\rho}{2}}$$

The friction loss is $.033\, N_o \frac{\pi Dn}{V}$. Hence the smallest brake horsepower possible is approximately

$$(2)\qquad N_o \left\{\frac{1 + \sqrt{1 + C_p}}{2} + .033\,\frac{nD\pi}{V}\right\}$$

The factor 0.033 refers to average conditions and to a lift coefficient of the blade of about 0.4 to 0.8. For smaller lift coefficients the factor is greater, and for higher it may be smaller, say up to $C_L = 1.2$, and then greater for still higher lift coefficients. This depends on the blade section.

The next step is the determination of the number and breadth of the blades. First, the lift coefficient is to be assumed. The highest lift coefficient occurring ought to be about 0.80 to 1.10. It can be said that the lift coefficient is fairly proportional to the thrust. Its value to be chosen is therefore in the neighborhood of T/T_{max} where T is the thrust for which the propeller is designed and T_{max} the greatest thrust ever occurring for the propeller.

The lift coefficient being chosen, the product of the number of blades and the average breadth of each blade is approximately

$$(3)\qquad i\,t = \frac{6\,T}{C_L \frac{\rho}{2} n^2 D^4 \pi^2}$$

This formula makes it possible to decide on the number of the blades and on their breadth.

The general layout of the propeller is thus finished and the design in detail can begin. First, the distribution of the thrust is to be decided upon. The coefficient of thrust is to be assumed, taking

Digitized by Google

(4) $$C_T = 1.1 \frac{T}{q\,D^2 \frac{\pi}{4}}$$

at 2/3 of the radius and

(5) $$C_T = 1.1 \frac{T}{q\,D^2 \frac{\pi}{4}} - \frac{2}{3} V/U\ C_D/C_L \frac{\pi n D}{V}$$

at the tip, where q is the dynamic pressure. For a very low velocity of flight, the last expression can be slightly decreased. This is, however, not yet the definite value of the thrust coefficients at these points. A diagram is to be drawn now, plotting the thrust coefficient against the radius. The two values just calculated are put in and connected by a straight line. Then the two ends of the curve so obtained are rounded off. At the outer end the rounding may begin, say 10% of the radius from the end, and the curve may end elliptically. At the inner end, the thrust coefficient is zero over the hub, and near it, only a small density of thrust can be realized, say

$$\frac{1}{2}\left(\frac{\pi n r}{V}\right)^2$$

or even the same expression with a factor smaller than $\frac{1}{2}$, if there are only two blades and these narrow ones. This gives a limiting curve inside, which is to be rounded off where it intersects the first one.

One must now see whether the curve of thrust coefficient thus obtained gives the desired thrust. The radius is to be divided into a number of equal parts Δr, say 10 parts. For each part the average value of the thrust coefficient is to be taken from the diagram and is to be multiplied by the radius r. All these products are to be added, and the sum A so obtained is to be multiplied by $2\pi\ \Delta r.\ V^2\ \rho/2$, thus giving

(6) $$T_1 = A\ 2\pi\ \Delta r\ V^2 \frac{\rho}{2}$$

This thrust will not agree exactly with the desired thrust T. Therefore all coordinates C_T are to be increased by the constant additional term $(T - T_1)/(.78\ D^2 q)$. Then they represent C_T for each blade element, and the section of each blade element and its inclination can be laid down.

For the choice of the blade sections the same rules are valid as for the choice of wing sections. The angle of attack for the desired lift coefficient can be calculated or it can be taken from a model test. In the last case the induced angle of attack $\frac{C_L}{\pi}\frac{t}{b}$ where b/t is the aspect ratio of the wing model, is to be substracted from the angle obtained during the test. The drag too is to be reduced to a drag for infinite aspect ratio, and an additional constant reduction of the drag coefficient making the minimum drag coefficient 0.02, will improve the result.

HUGHES

Let now δ be the difference of the angle ϵ of inclination of the blade element with respect to the propeller plane and the angle of attack β. This angle δ is to be determined by means of

(7) $$\tan\delta = V/U + \tan\delta\,(1 + V/U)\left\{1 + \frac{2\sin^2\delta}{C_T} - \sqrt{\left(1 + \frac{2\sin^2\delta}{C_T}\right)^2 - 1}\right\}$$

where U denotes $2\pi r n$. This equation is to be used by substituting an approximate value of $\tan\delta = 1.1\ V/U$ in the right-hand term. Sometimes the proceeding is to be repeated by substituting the value of $\tan\delta$ thus obtained. When $\tan\delta$ is found, the angle of inclination is

(8) $$\epsilon = \delta + \beta$$

and the chord of the blade is obtained:

(9) $$t = 4\sin\delta\ \frac{\tan\delta - V/U}{1 + V/U}\ \frac{2\pi r}{i\,C_L}.$$

For the analysis the following equations are used:

(10) $$\tan\delta = \frac{(\tan\epsilon\tan\delta + 1)\quad (1 + V/U)\sin\delta + \frac{4\ r}{i\ t}\ (\tan\epsilon\tan\delta + 1)}{\tan\epsilon\,(1 + V/U)\sin\delta + V/U\,\frac{4\ r}{i\ t}}$$

(11) $C_L = 2\pi(\epsilon - \delta)$. With some sections, C_L is slightly less.

(12) $$m = \frac{i\ t}{2\pi r}\ \frac{(\epsilon - \delta)\ \pi}{2}$$

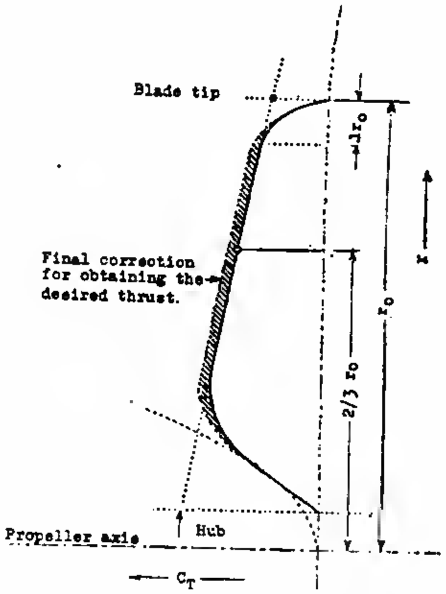
(13) $$C_t = \frac{4\ m\cos\delta}{1 - m\cos\delta/\sin^2\delta}$$

(14) $C_Q = C_T\,(\tan\delta + C_D/C_L)$.

(15) $$T\ \Sigma\ C_T\ 2\pi\ r\ \Delta r\ V^2 \frac{\rho}{2}$$

(16) $$\text{Torque} = \Sigma\ C_Q\ 2\pi\ r^2\ \Delta r\ V^2 \frac{\rho}{2}$$

Equation (10) is to be used instead of equation (7), assuming that $tg\delta$ lies between V/U and $\tan\epsilon$.



Harold J. Powers, Pioneer in Radio Broadcasting

Harold J. Power of Medford Hillside, Massachusetts, according to an article in a recent issue of the National Magazine, deserves credit not usually assigned to him as a pioneer in radio broadcasting. Mr. Power is the first man in America to have established daily broadcasting, according to this article. The radio historians wll have to decide between Mr. Power's station in this matter, and the Pittsburgh station of the Westinghouse Company (K D K A), which claims the same honor. True it is that Mr. Power did more than most men in putting radio transmission on a commercial basis.

Mr. Power was one of those boys who just can't keep their fingers out of father's tool chest, and who are everlastingly tinkering with the telephone, the electric light circuit, or anything about the house that will give the mechanical genius a chance to sprout.

"It was during a grammar lesson that I first became interested in radio," Mr. Power says, "copying the sentence in my copy book which ran 'Marconi, the inventor of the wireless telegraph.'"

The little boy, who was already very much interested in electricity, ran right home and began the business of building his own set. His first one stood on a table made from an old wooden box, and a wire strung from a post attached to the clothes pole in mother's yard constituted the antenna. The first message which he received (from the Boston navy yard) was the occasion in the middle of the night of an unceremonious rousing for all who had the fortune (or misfortune) to belong to the young experimenter's family or neighborhood.

"The story of Mr. Power's success," the writer of the article referred to, concludes, "is another proof that persistence is the forerunner to fame."

Tells How to Work Vacuum Tube Sets

Some good advice to the radio novice on the matter of adjusting and operating a vacuum tube set, always a troublesome matter even though the experimenter has constructed most of the elements himself, is given by Walter Remy in a book, "The Radio Primer," just published by Ralph T. Goodwin.

In explaining how to get results after the set has been correctly constructed and assembled, the writer says:

"After the tube was inserted in the socket the filament rheostat was turned until a slight hiss was heard in the phones. The tickler coil was set at an angle of 45 degrees with respect to the tuning coil and the variometer was rotated. If a click was heard, followed by a sound like that of escaping steam, the set was operating properly. With the receiver in this state the variable condenser was turned until a squeal was heard. This squeal is what is called the carrier wave of the radio telephone.

"The variometer was turned back again until the hiss and the squeal stopped and the variable condenser was moved a fraction of a degree until the radio phone was heard the loudest. The tickler coil was varied until the music or other signals were heard the loudest and the adjustment was left fixed. This adjustment did not have to be made again. The rheostat was varied to determine if any increase in strength of signal could be obtained. This latter adjustment was also permanent."

The new book is unusual in the recent outhurst of radio literature in that it stays close to its subject, which is the construction and operation of a home radiophone, explaining the theory of wireless when necessary through simple analogies.

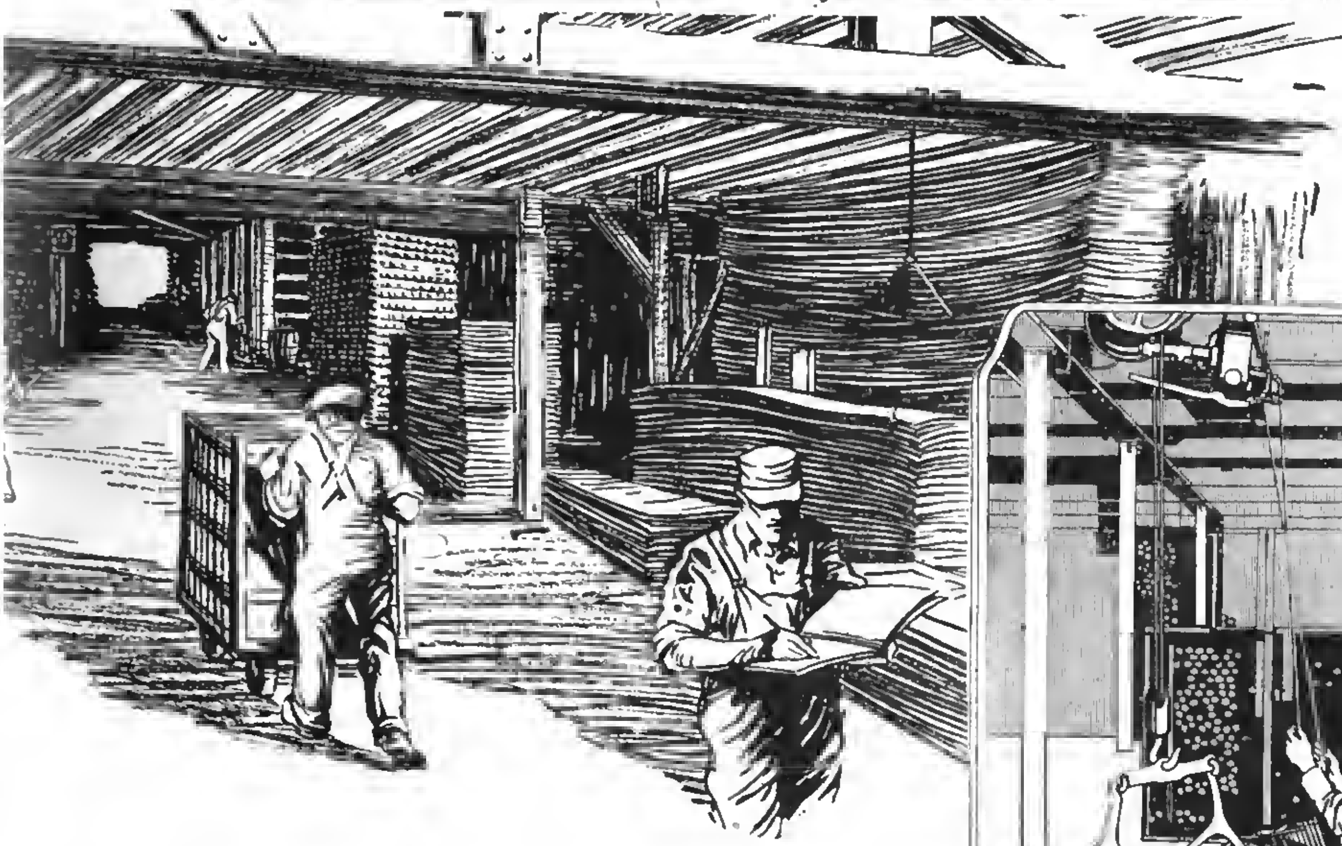
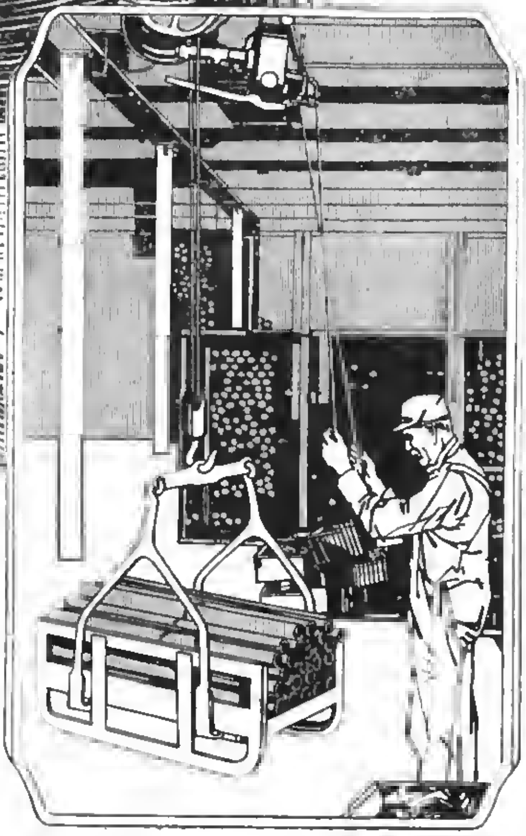
THE list of sales at the left is an index to offerings of materials you will want to investigate. Detailed advertisements of each sale will appear regularly in this publication and in other representative journals. Follow those advertisements and discover the benefits of the War Department as a source of supply. Check up the advertisements with this list and make sure no offerings are overlooked.

"The Government reserves the right to reject any or all bids."

WAR DEP





From War Department Sales to Your Production Needs

Stored in warehouses, the War Department has vast quantities of raw materials. They were bought to stand up under the exacting usages of war, and they match in quality the materials for which you are competing in the open market. The Government needs the money they represent, and they can be purchased for sums not duplicated elsewhere in value.

Here is a source of supply it will pay your purchasing department to investigate. Sales are conducted virtually every week by auction or sealed bid. Follow the War Department advertisements, write for catalogs of materials you can use, and participate in the sales.

NAVAL and MILITARY AERONAUTICS

Air Service Reserve Activities in Colorado

The headquarters of the 103rd Division, Air Service, was recently established in Rooms 210 and 213, Federal Building, Colorado Springs, Colorado. The office was opened up by borrowing a few small tables and chairs from the custodian of the building, pending the arrival of office equipment on requisition. A great deal of publicity was given concerning the establishment of headquarters by local newspapers, with the result that many inquiries were received from former service men and reserve officers located in and near the city of Colorado Springs. All who made inquiries were interested to know if, in joining the reserves, an opportunity would be afforded them to fly. All were anxious to get hold of the controls again and to keep up their training. The officer on duty with the Division Air Service at once set about to locate a suitable landing. field where he could invite visiting ships to land, the information found in "Notice to Aviators" for January 1, 1922, concerning a field in this locality, not being reliable. An excellent field was located, and permission to use same has been granted by the owner. With the assistance and co-operation of a local flyer, a 40-foot white circle was made in the center of the field, and a standard wind sock placed at one end of a pole. This information, with a sketch of the field, was sent to the Chief of Air Service; Air Officer of the 8th Corps Area; Post Field, Fort Sill, Okla.; and Kelly Field, Texas.

The organization of the 103rd Division, Air Service, as to the assignment of officers is just about complete, there being a few vacancies yet in the grades of Captain and First Lieutenant, and a surplus in the grade of 2nd Lieutenant. Enlistments for the 103rd Division, Air Service, have not as yet been undertaken due to lack of a clerk and office equipment and supplies. Hope is entertained that this deficiency will be supplied in the very near future.

Air Service Detachment Returns from Germany

The Air Service Detachment, consisting of two officers and 83 men, arrived at Mitchell Field on May 4th, from Germany. This detachment was apparently assigned to Mitchell Field to be broken up and the personnel distributed to other Air Service stations. This fact is regretted very much by Mitchell Field, because it is found that the detachment contains some very excellent soldiers and mechanics. The officers reporting with the detachment, 1st Lieutenants Dogan Arthur and Russell M. Greenslade, Air Service, have been ordered to report to Langley Field and Kelly Field, respectively.

316th Reserve Squadron Gets Under Way

After many trials and tribulations the 316th Squadron has finally gotten under way. With the assignment of Captain A. F. Harold to duty as Air Officer for the 91st Division, the final obstacle to actual work was removed. Two Hissos were acquired for the instruction of the pilots and an old DH for the instruction of the enlisted personnel. A staff sergeant and four specialists were detailed to temporary duty with the squadron.

Class instruction takes place every Monday night in the hangar which has been turned over for the exclusive use of the Reservists. On alternate Saturdays and Sundays practical ground instruction and flying takes place. The ground instruction is under Staff Sergeant Fowler (28th Squadron). The Specialists act as instructors in their respective specialties.

There are assigned for duty to the squadron 33 officers, leaving a shortage of only two for the full 100 per cent. Enlistments are being sought, it being the intention to enlist the men in a body when a complement of about 50 per cent of the authorized strength has been acquired. About 25 men are now taking instruction.

The 316th Photo Section has its full officer personnel, and is about ready to enlist its full quota of men.

Reserve officers have flown approximately ten hours during the week of April 25. A shortage of oil compelled the cessation of flying. Lieuts. Farmer, Kearny and Cavagnero have successfully soloed during the week. Hopes are being entertained that all the officers of the organization will take advantage of the opportunity and take a refresher course soon.

Post Field Fliers Visit Muskogee, Okla.

Fourteen ships (DH's) from Post Field, Fort Sill, Okla., paid a visit on Saturday, April 22, to Muskogee, where the Headquarters' 95th Division, Air Service, is located.

Major Thomas G. Lanphier, Officer in Charge of Flying at Post Field, with Captain Alexander Mileau, Flight Surgeon at Post Field, was in charge of the flight. Captains Vernon L. Burge and Frank L. Pritchard were the other officers of the permanent garrison making the flight. The following student officers of the Air Service Observation School, for whom the flight was a practice cross-country flight, were among those present: Captin De Ford, Captain Derby, Lieutenants Shrader, Vidal, Wisehart, Davidson, Stackhouse, Shen (Royal Chinese Navy), Cooper (Chile), Evert, Williamson, Peck, McBlain, Schabacker, and four mechanics.

Captain Charles B. Oldfield, Executive Officer of the 95th Division, Air Service, was on the field to meet the visitors. After all had arrived, Major Lanphier led a five-ship formation over Muskogee, with Captain Oldfield and Lieutenants Vidal, Shrader and Davidson following.

The secretary of the local Chamber of Commerce, Mr. Lydig, was on hand to greet the visiting fliers, as were also newspaper representatives and a number of citizens of Muskogee. Each visitor as he arrived on the field was given a complimentary card by the secretary of the Chamber of Commerce which entitled him to hotel accommodations at one dollar per day, 20 per cent off on all meals and free admission to the ball game.

Flying Activities at Carlstrom Field

The records of the Flying Officer at Carlstrom Field, Arcadia, Fla., show a total of 65 student officers and cadets under primary flying instruction during the month of April. A total of 5 officers and 13 cadets were relieved from further instruction during the month by the Academic Board. The total man hours flown during April was 2,174.55, aircraft hours flown, 1,480:20.

Elimination Contest at Scott Field

In preparation for the National Balloon Race to be held at Milwaukee, Wis., on May 31st, an elimination contest was held on Saturday, May 6th. Two balloons of 19,000 cubic feet capacity were used, the first piloted by Lt. J. W. Shoptaw, Chanute Field, with Lt. Courtland Brown as aid, and the second piloted by Lt. J. H. C. Hill, Scott Field, with Lt. James Healy as aid. Both balloons covered in the neighborhood of 110 miles, but Balloon No. 1, although holding a few miles advantage over Balloon No. 2, was in the air fifteen minutes longer. The race was so close that all data has been sent to the Chief of Air Service for his award.

Major Fitzmaurice Retires from Active Service

Major William J. Fitzmaurice, Air Service, who has been in command of the Montgomery Air Intermediate Depot since October, 1920, has been retired from active duty with the army, and will be succeeded in command by Major Roy S. Brown, commanding officer of the 22nd Squadron.

Major Fitzmaurice began his military career upon entrance to West Point Military Academy in 1904. He graduated therefrom in 1908, and was appointed a 2nd Lieutenant of Infantry. During his 18 years of service he has filled many important positions of responsibility. He saw foreign service in Alaska, Panama, France and Germany. It was while on duty in Germany that he met with a most severe and painful accident, which caused his physical disability and consequent retirement. A rifle he was using exploded, and particles of steel entered his right eye.

The last official ceremony, in which Major Fitzmaurice received the officers and troops in his command, was held on the morning of May 2nd. He addressed the men, expressing his satisfaction and appreciation of the cooperation from officers and men that has made the 22nd Squadron and the 4th Photo Section successful. He expressed regret at leaving the military service and in parting with the personnel of the depot and his many friends in Montgomery.

Major Fitzmaurice intends to make his home in Los Angeles, Calif., where his parents now reside.

FOREIGN NEWS

Aerial Map of Capetown

Taken after much patient manoeuvring by aeroplane, an aerial plan of Capetown's business centre has been photographed and issued for the guidance of all concerned, reports the *Cape Argus*. This novel guide is a reproduction of composite photographs of central Capetown, the leading buildings being neatly labelled. The result is a startlingly graphic map, which is unique, so far as South Africa is concerned. A key of the plan indicates more clearly the exact position of any given building, to which a number is assigned. Guided by the number in its sequence, the person interested can follow up his investigations at the foot of the plan. The map is published by Mr. Ken Donaldson.

The French Engine Competition

The regulations for the French contest for aero engines which is to be held during 1924 have just been issued.

This contest, which is due to the initiative of the Comité Francaise de Propagande Aeronautique, is supported by the Under Secretary of State for Aeronautics. The Committee and the French Air Ministry have each assigned a sum of one million francs for the purpose of the competition.

The million allocated by the Government is to provide two prizes each of 300,000 francs for engines of French origin, and the million allocated by the Committee is to be devoted to purchasing for the benefit of the French Government the French manufacturing rights in the engine which is adjudged to be the best. Engines of any origin—except those from ex-enemy countries—are eligible for the competition, but not for the two prizes above mentioned as reserved for French engines.

In the event of the winning engine being of foreign origin, in addition to the sum of one million francs, provision is made for the payment of royalties at a maximum rate of 8,000 francs per engine for the first 100 engines built, decreasing 1,000 francs at each 100 engines till the 600th, whereafter a uniform maximum royalty of 2,000 francs per engine is payable.

Entries will be received up to December 1, 1922, by the Commission d'Aviation of the Aero Club of France if accompanied by an entrance fee of 20,000 francs. Entries will be received up to December 1, 1923, at an entrance fee of 40,000 francs. Foreign competitors will in addition be required to contribute 10,000 francs toward the cost of testing.

Half of the entrance fees will be returned to all competitors who pass the eliminating tests. The special contribution of 10,000 francs from foreign competitors will be returned to those who may withdraw before the official opening of the trials.

Engines must be of the internal combustion type, and of a normal output of between 350 and 450 h.p. The weight per h.p., including the weight of fuel and oil for 5 hours, must not exceed 3.3 kg. per h.p. The speed of rotation of the airscrew is not to exceed $\frac{32,000}{\text{V.H.P.}}$ r.p.m.

All engines are to be fitted with a self-starter such that the engine may be started at a distance without turning the engine by hand. This starter alone is to be used for starting during the whole of the trials.

Engines will be required to undergo eliminating trials, including five hours' run on an air brake on the test bed, and two hours' flight on an aeroplane which is to be provided by the entrants.

Thereafter the engines will be submitted to an endurance test totaling 240 hours' run in thirty periods of 8 hours each on the test bench. The load is to be an air brake of the airscrew type, supplied by the competitor, and the engine will be mounted on a pivoted test bed, which will allow measurement of the brake h.p.

The total of 240 hours' run is required to be made in not more than 100 days—not more than one run per day—and penalty marks will be awarded for every delay in starting, for every stoppage during a run, for every day taken to complete the tests in excess of the possible minimum of 30 days, and for every repair and replacement made during the whole period. Any individual run may be annulled on account of delays in starting, stoppages, or failure to develop the required power.

The whole endurance test may be annulled if more than 10 such runs have been annulled, if more than 30 days elapse between any two consecutive 8-hour runs, or if the total of repairs or replacements exceed certain specified limits.

A second attempt may be made, but is to be completed in 80 instead of 100 days. Such a second attempt is attended by penalty marks.

Marks are to be awarded for the weight per h.p., with five hours' fuel and oil, as determined from the actual consumption and power developed during the trials. If the weight per h.p. so computed is more than three k.g. per h.p. the marks are penalties; if less, they are set against penalties.

Penalties are inflicted for the air resistance of the engine, which is taken as proportional to the area inside the smallest convex contour which will entirely enclose the projection of the motor on a plane normal to the airscrew axis. This area, divided by the normal full power of the engine, is the basis of the penalty marks.

The sum of all penalties, less any good marks for low weight per h.p., will serve to classify the competitors, the lowest total being that of the winner. One of the 300,000-franc prizes for French engines will be awarded on this same basis. The second 300,000-franc prize will go to the French engine which gives the best results on the two points of weight per h.p. and head resistance.

Complete details of the rules, conditions of entry, and so forth, may be obtained on application to the Commission d'Aviation de l'Aero Club de France, 35, Rue Francois 1er, Paris.

The system of penalty marking laid down in the regulations for this competition has certain very interesting and somewhat ingenious features. The system has obviously been devised with the intention of eliminating so far as is possible the effects of accidental ill-chance on the prospects of a good engine, and of penalizing very severely any form of consistent ill-behavior.

Penalties are imposed for all delays in starting, and for stops during test runs. These penalties vary with the time of delay or stop. If the delay does not exceed one hour, if there is not more than one stop in a run, and that stop is of less than one hour, the penalty on the score of stop or delay goes no further. But if either stop or delay exceed one hour, or if there is more than one stop, the run is annulled. There is a penalty for annulment, and in addition a further penalty for the extra day taken to complete the 240 hours' total.

And if the stop or delay involves the repair or replacement of any part there is a penalty for that repair or replacement. This penalty is inflicted for repairs, etc., even if it does not lead to delay or stoppage. The penalties are thus cumulative, and increase as their effects become more serious.

But the method of penalizing for repair and replacements is extremely ingenious. There is a basic scale for these, the penalties increasing with the time needed to carry out the work, whether the work is of a nature which allows immediate resumption of the test, or necessitates "tuning up" and preliminary running before continuance of the tests. Also generally the penalties for the replacement or repair of an isolated piece are less than are those for a complete unit. That is, it is cheaper to replace a big-end bush than a complete connecting rod unit, and it is cheaper to replace an accessory unit such as a magneto than an essential of the engine, such as a complete cylinder. This is quite apart from penalties which arise from the delay in carrying out the change.

But the basic scale applies only to the first time of repairing or changing a given unit or type of unit. Wherever a part has already been changed or repaired the penalty for change or repair to a similar part (not necessarily the same part) is to be that in the scale, multiplied by the total number of changes or repairs to the same part or type of part. From this rule plugs and valves are excepted. In their case the penalty is imposed plus the number of preceding replacements.

The effect of this rule is that the tenth defective water or oil joint to be replaced during the tests will involve a direct penalty as great as that due to the changing of a crankshaft or cylinder. Thus silly little failures due to faulty design or workmanship which recur continually are very heavily penalized, while a more serious breakage which may be due to an undiscoverable flaw or to some accidental mischance does not necessarily put an engine out of the contest.

Aerial Transportation in Europe

Consul Dreyfus, Dresden, reports to the Department of Commerce that on April 1, a daily passenger, mail, and freight air service was re-established on the line Dresden-Berlin-Hamburg and return; also on the line Dresden-Leipzig-Magdeburg-Hanover-Bremen and return. The trip from Bremen to Hamburg takes four and one-half hours, including a half-hour stop in Berlin. The journey to Bremen requires five hours, including 15-minute stops at Leipzig, Magdeburg, and Hanover.

The fare from Dresden to Berlin is 500 marks and from Berlin to Hamburg 650 marks. This compares with 285 marks and 387 marks, respectively, for the first-class railway fare between the same points. Passage from Dresden to Leipzig is 500 marks and from Leipzig to Bremen 1,300 marks, as compared with 190 marks and 536 marks, respectively, for first-class railway fare between these points. Fifteen kilos of baggage is carried without charge, and all excess at the rate of 15 marks per kilo.

It is reported that a service from Dresden to Prague will be inaugurated in June.

Acting Commercial Attache Cross, Brussels, reports that the "Sneta," a Government-subsidized aerial transportation company in Belgium, has finished its trial period of passenger, merchandise, and postal aerial transport service between Brussels and cities in neighboring countries (Paris, London, Amsterdam, The Hague). Belgian participation on these lines will, therefore, cease from June 1, 1922, leaving the Paris-Brussels and Brussels-Amsterdam services in the hands of French and Dutch companies. A Brussels-London service will be organized by an English company, beginning in May of the present year.

The Belgian Government is studying the creation of a permanent organization which will permit that country to conserve an important position in international aerial transportation.

London-Brussels Service Inaugurated

May 8 saw the inauguration of the new aerial passenger and goods service between Croydon and Brussels, which is being run by the Instone Air Line, under the Government subsidy. The first machine, D.H. 34 G-EBBT "City of New York," piloted by Mr. Barnard, and with passengers, left the terminal aerodrome at Croydon shortly after 10.30 a.m., the departure being witnessed by the Hon. Capt. Guest, Minister for Air; Major-Gen. Sir Frederick Sykes and many other well-wishers of commercial aviation.

This flight was only in the nature of a preliminary trip, a regular daily service being arranged to start on Monday next. It is of interest to note, however, that permission to fly over the Royal Yacht, on its way across the Channel, in connection with the Royal visit to Belgium, had been granted by the King. The machine arrived safely at Brussels at 12.50, having taken two hours two minutes to complete the journey—quite good going. The return trip to Croydon was made later on the same day; photographs for the press of the Royal visit in Belgium forming an important item carried on the machine.

Owing to the engineers' strike, delivery of new machines has been considerably delayed, but it is hoped that before long the Instone fleet will comprise ten passenger machines and two specially built cargo machines, when a regular and frequent service to and from Brussels will be run without in any way interfering with the London-Paris service. Arrangements are being made to book through passengers *via* Brussels to all parts of the East by air. Passengers will be able to go to Brussels by air, spend a few hours, and return to London the same day—which should be a great boon, not only to tourists, but to commercial and business people. It is also the intention of the Instone Air line to run a service to Ostend during the summer months, whilst negotiations are taking place with the diamond merchants to run a "special" once a week to Antwerp, returning the same day.

The London-Brussels route will prove to be an extremely useful one, for Brussels should form an important junction for the various lines to Northern and Central Europe.

Rio de Janeiro and Porto Alegre Air Service

The Brazilian Government has been authorized to establish two aerial routes and air craft services between the cities of Rio de Janeiro and Porto Alegre, an overland route for aeroplanes and a seaplane route along the coast. Both of these routes will, it is proposed, be ready by September, 1922. Although the routes are intended primarily for use by the military and naval forces, and will be organized and controlled by the Ministry of War and the Ministry of Marine, respectively, the facilities they afford will be available for civil purposes, subject to the consent of the Government being obtained, and the payment of a fee and charges for material used.

The Decree authorizes the Government to borrow, up to a maximum of 4,000,000 milreis, to cover the cost of the scheme.

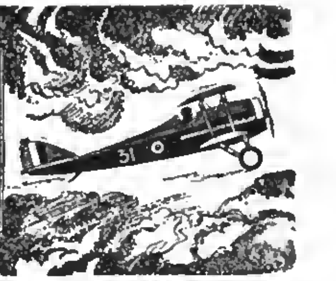
ELEMENTARY AERONAUTICS *and* MODEL NOTES



Scale Models Constructed by Aerial Age Readers

Curtiss JN4D built to scale of 1 inch to the foot

Patterning his model after a JN plane owned by the North-Eartern Aeroplane Co. of Rochester, N. Y., Walter M. Fitch of Canadaigua, N. Y., has completed a scale model which is one-twelfth the size of the original. Great care was taken to carry out all the details and the result is a realistic reproduction. Our readers will recall the Thomas-Morse Scout model built by Mr. Fitch, and illustrated in the January 2d issue of AERIAL AGE.

The description of the JN4D is as follows:

Wing span	43½ inches
Length over all	27¼ inches
Wing chord	4⅞ inches
Gap between wings	5 inches

Fuselage

Longerons are of ⅛" spruce

The cockpits have aluminum seats padded with patent leather. The controls are only in the forward cockpit. On the dashboard of the front cockpit are tiny reproductions of the following instruments: Altimeter, Tachometer, Clock-Compass and very small dials to represent the oil and water-pressure gauges. Both cockpits are equipped with throttles and "sparks" which were cut from aluminum.

Celluloid wind shields are placed in front of both cockpits and rubber tubing padded with fine silk is used to imitate the padding on the big ship. A dummy gasoline gauge is in front of the wind-screen of the first cockpit.

The motor cowlings have openings cut in the usual shape. inspection doors open and are hinged on the inside by means of adhesive tape.

Motor Group

The propeller is patterned after the "D-5,000" type, the kind used on the JN. The "prop" has 5 laminations which are each 1/32" in thickness. The aluminum flange has 8 tiny nails in it to imitate the bolts on the real plane and the hub has a tiny bolt to give a realistic effect.

The radiator was cut from a piece of white-wood. It has 4 lines of wiring to give the "honey-comb" appearance.

Each cylinder was made separately. Rocker-arms were made on strips of aluminum carefully bent and the springs were made of coils of very thin wire.

The eight cylinders were all glued to a piece of ply-wood attached to the upper longerons.

Intake pipes are of ⅛" round wood.

Exhaust pipes are of ⅛" material also and are painted black, but the remainder of the motor is given a coat of grey aluminum.

Undercarriage

The struts of the landing gear are carved from white-wood; streamlining is carried out and silk thread wound around at the proper intervals to imitate the linen thread material which is on the big aeroplanes to strengthen the struts.

Axle is brass, the wheels aluminum with pneumatic tires, and the thin strands of rubber band act as shock-absorbers.

The tail-skid also shock-absorbs and has a "shoe" of aluminum.

Empennage

Control horns were cut from white-wood.

Single strand wire is used to brace the control pylons and the wires running from the control horns are double twisted in order that the wiring may appear like stranded cable.

The hinging is carried out in the same manner as on the large plane.

Stabilizer braces were cut out from ply-wood.

The rudder is painted a blue, with the letters, "2 ROCHESTER, N. Y.," in black.

Panels

The wings are made of bass wood; the ribs being made to scale of the "Eiffel No. 36" wing curve. Near the tip of the trailing edge of the lower left wing the angle of incidence is decreased and on the right wing vice-versa, this done to give the "wash-out" and "wash-in" effect. The "sidewalks" on the lower wings are made of aluminum. The wing-skids are of reed, steamed to the proper shape.

The wiring on the wings is carried out in detail, the landing wires being single, the flying wires double.

Aileron cables are of waxed thread in order to insure good working order. Aileron wheels are made of ply-wood and are ¼" in diameter.

Each upper wing has 18 ribs and the lower 14, as on the big ship.

Over each rib (on wings and empennage) is glued a strip of paper roughed on the edges to represent the frayed cloth which covers the ribs on the original.

Struts are made of white-wood and numbered to indicate their proper location, as on the big ship.

General Notes

The model is painted with the Army "OD" color, which is a greenish khaki, but the rudder and circles on wings are blue.

All the struts are stained with 2 coats of light oak.

Lastly, the model is finished off with a coat of very thin varnish.

A Curtiss-Navy Racer Model

Mr. Bartle J. Allen of 681 Orchard Avenue, Bellevue, Pa., followed the outlines and suggestions for building a flying scale model of the Curtis-Navy Racer as published in the February 13th issue of AERIAL AGE.

Although no long distance flights have been accomplished, the model has "hopped" from forty to fifty feet.

With little additional weight, the fuselage was coated with aluminum paint which adds very much to the appearance. In order to secure the maximum efficiency, a standard propeller was used.

The balsa body is a very light and strong construction, weighing only a little over two ounces. Although very light construction methods were followed throughout, the model is very strong and effective.

The National Scientific Society

The National Scientific Society, founded at Cooper Union, consists of students of Chemistry and Engineering. Among its various departments, the "Aircraft" and "Radio" departments are in majority. It is a society founded for the purpose of "creating and fostering a craving for things scientific" and "to assist, financially and morally, any one or group of members who may be engaged in research or experimental work in any phase of Engineering or Chemistry."

The following is the progress of its "Aircraft Engineering Department":

The membership of the department has reached forty-five, and is rapidly increasing.

Ten models have already been completed and are ready for experimentation. The models consist of rubber power-plant and otherwise.

The department has procured the use of the Cooper Union Laboratories.

Arrangements are being concluded between the society and various model aircraft clubs over the world for the purpose of formulating laws so that international competitions may be held on model aircraft on a recognized basis.

Communications are invited from model clubs, particularly collegiate clubs, to join in this alliance.

The society invites communications from any model aircraft clubs interested in international competitions.

All correspondence should be addressed to Mr. Jacob J. Kuscher, president, Chapter Alpha, National Scientific Society, Cooper Union, New York City.

RADIO DIGEST

Government Revenue for Radio Messages Increases

The revenue derived from private and commercial radio messages dispatched from Government stations shows an increase of 2,000 per cent in 1921 over the year 1917. The earnings of these stations is estimated to be in excess of $1,600,000 and shows a profit of more than 15 per cent on the Government's investment of $25,000,000.

In 1917, the first year in which commercial and private messages were transmitted by the Government, the amount received from this source was $32,249.34. In 1918 this revenue was increased to $291,903.03; $221,171.79 in 1919, $641,584.90 in 1920 and $666,362.44 last year.

Approaching Storms Detected by Radio Lose Their Terror

Detection of approaching thunder storms in time to make necessary adjustments in operation of electric service is a valuable practical use of the radio, according to the report of the electrical apparatus committee of the National Electric Light Association presented at the convention in Atlantic City. The radio also serves to detect defects in electrical apparatus and equipment more efficiently than any other agency, the report says.

"The entire radio art has reached an eminently practical and dependable stage," the report continues. "Transoceanic telegraphy on a basis comparable to that of the cables probably represents both the greatest investment and the most spectacular operation. The marine use of radio, including not only ship communication but also position finding for vessels at sea, is of tremendous importance. In Europe wireless telegraphy is coming into extensive use for intercity communication. Some attempts in this direction have also been made in the United States.

"The broadcasting of news and weather dispatches, musical and other entertainments, speeches and church services by radio telephone is providing a valuable service to hundreds of thousands of listeners. Radio has also proved its importance as a wire line auxiliary in the radio field. Train dispatching by radio has been accomplished many times, and some far-seeing railroads have installed radio equipment as part of their permanent plant."

Communication between plants and substations, transmission of instructions to repair gangs along the lines and the possibility of the remote control of switches are given as some of the immediate and important applications. Installation of receiving outfits on automobiles and motorcycles is made where portability is desired. A wide field for remote operation of substations and switches is opened by the application of what is known as the "wired wireless."

"Not the least interesting outgrowth of radiant-wave telegraphy," says the report, "is the application of its principles to communication along wires. It has been found entirely feasible to associate a radio transmitter with a wire system running from one point to another (even though that wire were used for power transmission) and to send along the wire a series of radio-frequency current waves which may be detected at the distant end by means of a simple radio receiver. Such 'wired wireless,' as the arrangement is frequently called, permits considerable economy in operation. It is claimed for this system that fairly clear telephone communication is possible even with lightning storms over the main line and with all but one of the power wires cut or grounded."

Within the last year, and even in the last few months, a number of steps which mark notable progress in radio have been made, the report says.

"Both transmitters and receivers have been improved in effectiveness, economy, reliability and convenience of operation. In radio telephony substantial improvements have been made in clarity of speech transmission, so that now the radio gives a definiteness of articulation far surpassing the wire telephone. Loud speaking apparatus has been developed to the point where purity of reproduction is not sacrificed to gain sufficient intensity. It is now possible to secure reliable radio service of a character never before even approximated."

Nation's Time Governed by Radio Daily

Shortly before 10 o'clock, Eastern Standard time, every evening in half a million homes the ticking of a distant clock is now heard, and the time of as many citizens is daily regulated by it. The ticks come from the clock in the Naval Observatory and are transmitted through the famous long-distance station at Arlington, Va.

Not only do these ticks regulate the nation's clocks throughout the Eastern section of the country, but they also figure very materially in the navigation of practically every steamship plowing its way across the waters of the Atlantic.

How are these signals sent out so regularly and consistently, and how are they reproduced from the broadcasting stations? That is the question that is of the greatest interest to the radio fan.

In the first place, the signals themselves are produced by the clock in the Naval Observatory in a very novel manner. The pendulum on the clock, swinging across its arc of travel, makes contact with a piece of metal every time it passes through its perpendicular position, and it is so arranged that it makes one complete swing every second.

As the pendulum passes across the contact it closes a local circuit, which in turn operates the transmitting apparatus at Arlington and thus sends out the brief dashes that are so familiar.

Now, as is well known, these signals are sent out on a wave of 2,600 meters in length, while the broadcasting stations are operating on 360 meters. The consequence is that the broadcasting stations which reproduce them must actually receive and transmit at the same time.

This fact is not generally appreciated by the average radio fan, and it offered a very serious problem to solve, especially as it was desired to reproduce in all faithfulness the exact note of the Arlington station. It must be realized that in the case of the broadcasting station the receiving aerial is not more than a few feet away from the transmitting aerial. The problem, therefore, was to eliminate the inductive and radiation effect of the transmitting aerial from the receiving aerial so that it would not interfere with the true note of Arlington.

Another difficulty that had to be overcome was the amplification of the weak signals received from Arlington without distorting them or changing their characteristics, because as received they were too weak to operate upon the transmitting apparatus of the broadcasting station.

I have listened several times on sets so arranged that it was possible to change quickly over from the 360-meter wave length to the 2,600-meter wave of Arlington, and the astonishing thing was the wonderful exactitude of the reproduction from the station broadcasting.

At the broadcasting station radio amplification is used to build up the current received in the antenna there before it is passed for rectification through the detector tube. The audible frequency of the Arlington quenched spark is then passed through audio-frequency amplifiers, and finally delivered into a special telephone receiver.

This receiver is attached to a telephone microphone transmitter of special design, and then placed into the modulator tubes of the transmitting apparatus and reradiated on the 360 meter wave, so that all of the radio fans listening on their short wave receivers can obtain the correct official time every evening.

The remarkable thing about the whole transaction is that there is absolutely no loss of time in the transference from one wave-length to the other, and this is a very important factor to those who desire to set chronometers by means of the short wave reproduction of the time signals.

The manner in which the signals are transmitted from Arlington is as follows: The ticks are reproduced, starting from 9:55, Eastern standard time, every evening. Each second is sent out as a short dash, which is reproduced in the telephones. The tick of the twenty-ninth second of every minute is skipped, leaving quite a distinctive space. At the end of each minute the signals are omitted for several seconds, making a longer pause. At the end of the fifty-ninth minute after 9 o'clock the signals are omitted for ten complete seconds, which, of course, is much more noticeable. This longer pause also permits the operator of the broadcasting station to announce over the 360 meter wave his famous: "The next dash will be 10 o'clock."

One of the officials of a broadcasting station made the following suggestion:

"A convenient way to check your watch is to follow the second hand during the first part of the signals, thus noting the position of the second hand relative to the end of the minute. The minute hand should be observed during the fifty-ninth minute and checked with with the signal for 10 o'clock. In this way you can tell exactly how many minutes and seconds your watch needs to be changed in order to absolutely correct time."

Radio Cuts Message Cost

It is estimated that by using radio to keep in touch with various army headquarters and posts the War Department will reduce the communication expense more than 40 per cent. Formerly all offi-

Digitized by Google

cial messages were dispatched over the wires of the commercial telegraph and telephone companies. Radio now is used almost entirely.

Double Circuit Set Reduces Interference

How can I eliminate interference from other stations? That is the question which bothers most of the radio fans, and the answer to it is bound up in the construction of the receiving set itself. A large number of sets now on sale, and in use employ what is known as a single circuit receiver. They have been so designed because of the desire to give to the novice an instrument that will be as simple as possible to operate and to adjust. For the purpose of selectivity, however, such a set is not nearly as efficient as a double circuit receiver.

In this article, I propose to outline the functioning of the double circuit set and in doing so it will be necessary to describe the vario-coupler and the loose coupler and explain the manner in which both of these two instruments operate. It will be helpful to those who are making or assembling their own equipment, as well as to those who have installed sets that are manufactured complete. In the first place, with a double circuit receiver, we have two complete and independent circuits, as the name naturally implies. The first is the aerial or antenna circuit, which consists of the aerial and an aerial tuning inductance and a ground connection. In some cases, the addition of a condenser in series with the aerial and the tuning inductance is included. This description of the aerial circuit sounds imposing, but in realty it is very simple and merely consists of the aerial wire and then the primary winding of the vario-coupler, or the loose coupler —whichever is used.

The next circuit is called the secondary circuit and consists of an inductance and a condenser. Now these two circuits taken together form what is technically known as oscillating circuits, or in plainer language the circuits which handle the high frequency currents pcked up out of the ether.

The object of using two circuits is as follows: By carefully adjusting the aerial circuit we set it into resonance with the station we desire to listen to, just in the same manner as two tuning forks pitched to the same tone are in resonance with each other. In the natural course of events, however, every electro magnetic disturbance in the ether passes over the aerial to the ground. If the aerial circuit is not in resonance with any particular wave, it will not oscillate to it—that is, theoretically it should not do so. In practice, however, we find that it does, and this is the cause of interference which of course will be recorded into telephone receivers where only a single circuit is being used. Now, with the addition of a secondary circuit, which is also carefully adjusted, we eliminate still further the possibility of interference by increasing the number of circuits that have to be in oscillating resonance with each other.

There are two main methods of installing a double circuit receiver—one is by the use of a loose coupler, which is now more or less discarded, and the other is by means of the vario-coupler.

The loose coupler consists of a primary inductance, which is nothing more or less than a wire wound around an insulated tube in such a way that we have a certain number of turns on the tube. The more turns of wire there are upon the tube, the longer is the wave-length that it will respond to.

The secondary of a loose coupler consists of a winding on another tube, which is so arranged that it will slide in and out of the primary tube. In fact, it will come completely out of the tube, and can be pulled away quite a few inches clear of the primary tube. In this manner we have three possible adjustments—first, the number of turns on the primary that we can bring into play in the primary circuit; second, the number of turns that we are bringing into the secondary circuit, and finally the inductive relationship between the two coils themselves, which is technically known as "close" or "loose" coupling. The object of this loose coupling is to eliminate the effect of interference by loosening the coupling between the two coils. It has been found in practice that when the primary and secondary circuits are in resonance with each other the two coils can be separated quite a distance and signals still be recorded in the telephone receivers, whereas signals that are not in resonance with the circuits will be eliminated by widening the coupling between the two coils.

Experience, however, showed that there was a considerable inductive loss when loose coupling was used and this led to the development of the vario-coupler, which is a much more efficient instrument. It has this drawback, however, that the secondary winding is not variable, but this is overcome by the addition of a variable condenser placed across the ends of the secondary coil.

Now the vario-coupler consists of a primary exactly the same as the primary of the loose coupler, although it is invariably wound on a tube of larger diameter. The secondary is wound on a ball, or rotor, which is so arranged inside of the primary tube that it can turn around in a complete circle. When the windings of the secondary of the vario-coupler are exactly parallel with the winding on the primary, there is a maximum induction between the two. This induction is decreased by turning the secondary, or rotor, in such manner that the windings assume an angular position in relation to the primary winding. This has the same effect as withdrawing the secondary in a loose coupler, but it has the advantage of not taking the secondary coil out of the maximum electro-magnetic field, and in this manner we obtain much greater efficiency in operation.—Jack Binns in *N. Y. Tribune.*

How to Keep Radio Safe in Lightning

One of the most debated questions among radio amateurs and broadcast listeners is whether a man who hangs out an aerial hangs out at the same time an invitation to every lightning bolt in the vicinity to come and pay him a visit. The warmth of the debate reaches its greatest height when one of the participants is the unscientific but forceful landlord of an apartment house and the other is a tenant.

The question is answered by G. K. Thompson, radio superintendent of the American Radio and Research Corporation, as follows:

"You should harbor no fear that your radio installation will attract lightning. The chances of lightning striking your home this summer are no greater than the chances last summer. You should make it a point, however, to install such safety devices as will render harmless the currents induced in your antenna by lightning bolts striking in the neighborhood."

Mr. Thompson, in discussing lightning, divided the subject into three parts, the protection of the house, the operator and the set.

He suggests for the house the installation of a lightning switch or a grounded short gap of approved design, avoiding the purchase of slate base, switches, gaps or other devices, which do not support the ground conductor at least five inches out from the wall of the building. A good ground conductor should be used, running directly as possible to a good ground connection, such as a water pipe.

"Have the installation approved by your local inspector," he advises, "so that in case any damage to the building by lightning ever comes to pass, the validity of the radio installation will not be questioned."

In considering the protection of the radio set itself from possible damage from heavy electrical discharges Mr. Thompson says:

"The best precaution to follow is to disconnect the antenna and ground lead wires from the terminals of the set before the thunderstorm breaks. If you do not care to disconnect the set a protected gap should be purchased and connected across the antenna and ground terminals on the instrument. A substitute for such a gap can be provided in the form or a burnt out flashlight bulb screwed into a miniature base, the terminals on the hase being permanently connected to the antenna and ground terminals of the receiving set. If the latter terminals are mounted close together a discharge gap may be provided by clamping two ordinary sewing needles in the terminals, separating the points by the thickness of a piece of paper. For maximum protection, however, complete disconnection of the receiving set from antenna and ground connections is advised."

These suggestions are made for personal safety:

Don't attempt to operate the set while a local thunder shower is in progress. You can hear nothing but static discharges, the elimination of which is entirely beyond your control.

Don't touch the ground wire or the antenna lead wire while the storm is in progress.

If you use a lightning switch don't touch it while the storm is in progress, even though it may not be set in the grounded position.

Fire Department to Install Radio

Fire Commissioner Drennan of New York City has given his official sanction to the installation of radio receiving apparatus in the fire houses of the New York department, subject to regulations.

A number of the fire houses have judiciously had receiving apparatus which the men had purchased and installed that there has been some division of opinion as to the property of such equipment on city owned property without official approval.

In his approving statement Commissioner Drennan points out that radio will furnish diversion and healthy recreation for the firemen and help to relieve the monotony of engine-house life.

Apparatus may be installed at the expense of the firemen themselves, after written applications containing a sketch of the plan of the proposed installation has been approved by the chief of the Bureau of Fire Alarm Telegraph, Mr. Val Fendrich, and also by the Department of Water Supply, Gas and Electricity, which has jurisdiction over all electrical appliances in public buildings.

No broadcasting or transmitting sets will be allowed in the fire houses.

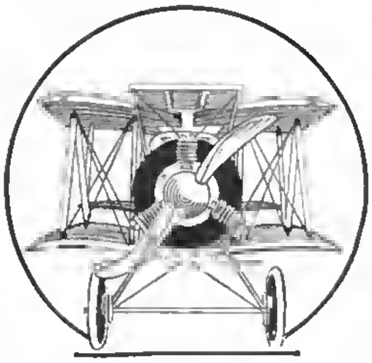
The New Longren Airplane



The illustration above shows how the wings of the Longren Airplane may be folded back for housing purposes, without disturbing the setting of the wings or controls.

DESIGNED by A. K. Longren—one of the pioneer airmen of the West—the New Longren Airplane meets all demands for a safe, rapid and comfortable plane, to be cared for and operated by the owner.

This new plane is pleasing in appearance—simple and sturdy in construction. Its operating cost is low. Folding wings make housing a simple matter. It has a quick take-off with rapid climb, and responds instantly to the controls.

Only the highest-grade materials are used in the manu facture of the New Longren Airplane. In a recent letter to us Mr. W. D. Wallace, Secretary of the Longren Aircraft Corporation, says: "We use Valspar exclusively, for the very good reason that after exhaustive tests, we were unable to find any varnish or enamel that could compare with Valspar and Valspar Enamels."

Learn to Fly

Aviation is making such strides that it needs more men right now

You Can Learn To Fly

I can teach you how to become a successful pilot in a short time. My course is so arranged that you get only the things you need to make you a good aviator.

The Diggins Extension Course

is up-to-date, teaches you what you must know to become an expert flyer. This course is written by competent instructors right on my flying field. It is kept right up to the minute—all new developments in aviation are included. That is why it is recognized as the most complete and practical course offered today. My course saves you time and money because it prepares you at home so that you are ready to begin flying the day you arrive at the flying school.

Superior Points of the Diggins School

1. The Diggins school is the oldest, largest and most complete commercial aviation school in America.
2. The Diggins school is located in Chicago, the center of Aviation.
3. Living quarters and free employment service are maintained for students.
4. Diggins guarantees to make you a pilot.
5. Diggins' pilots get top notch salaries.
6. References, any aero club in America.

WRITE TODAY Write today for the new Diggins beautifully illustrated catalog.

veniently organized as a committee of International Chamber of Commerce established in 1920 after the Congress called at Atlantic City in October, 1919. The main function of this organization should be to coordinate the work of the various aeronautical Chambers of Commerce, aero clubs and similar organizations throughout the world.

The constructive work which could be accomplished by both the international organ of coordination of aeronautical Chambers of Commerce, aero clubs and other aeronautical organizations is simply invaluable. All matter pertaining to international regulation of flight, standardization, licensing of pilots, testing of aircraft, wireless and meteorological services, organization of airdromes and airways, rules for complying with costume and passport regulations, transhipment of mail, passengers and merchandise, could be thoroughly investigated by specialists and satisfactorily settled. These two organizations would be of tremendous help to the various governments in suggesting the right kind of legislation needed to promote and to further the development of aeronautics all over the world.

In the meantime, while we have not any such organization it is up to our aeronautical Chamber of Commerce and to the Aero-Club of America to do whatever they can in order to encourage commercial aviation developments in this country, to keep us closely in touch with the aeronautical situation all over the world and to cooperate to the best of their ability with similar organizations in Europe for promoting a true spirit of international cooperation between aeronautical interests in the world on matters of common interest, this being the condition *sine qua non* for succeeding in putting aeronautics on the map of the world as a practical and safe international means of transportation.

However, more than anything else, what we need at the present time is to get started, to stop discussing projects with regard to commercial aviation developments, and to actually start something. As I said before, the logical start is the inauguration of a regular service for the transportation of mail and merchandise between New York and Chicago, with the right flying equipment bought in the United States at the right price from aircraft manufacturers having sufficient faith in the quality of their aircraft to be willing to become stockholders in the company operating them. After this company has been started right, let all the financial groups interested in commercial aviation developments in this country concentrate their efforts in building it up and making it the corner stone of our commercial aviation activities.

Let us not have competition in the beginning of this game—there will be plenty of opportunities for promoting developments in the future through competition. What we need for the first year or two is cooperation: cooperation between financial interests in creating first a strong aerial operating company; the cooperation of the government, express companies and the public at large in patronizing this new means of transportation; the cooperation of aircraft manufacturers in providing good aeroplanes; the cooperation of the communities in providing landing fields; and the cooperation of Congress in enacting without any further delay the right kind of air legislation.

If the first aerial transport company is able to start operating under these conditions, inside of a few years we shall lead the world in commercial aviation developments.

HARTSHORN STREAMLINE WIRES
Assembled with Hartshorn Universal Strap Ends make the Ideal Aeroplane Tie Rods—diminished wind resistance insuring greater speed.
This fact was proved in the speed test for the Pulitzer Trophy. Four of the first five ships were equipped with Hartshorn Streamline Tie Rods.

CHAMBERLIN AIRCRAFT

NEW YORK AIR TERMINAL

HASBROUCK HEIGHTS, N. J.

5 SEATERS—$2000.00 to $2500.00
DH-6 and J-1's with Hispano or 150 Clerget

3 SEATERS—$950.00 to $1500.00
Avro with 110 H.P. Le Rhone or 130 H.P. Clerget and DH-6 with OX5, OXX6, 95-110 Anzani or 6 cyl. Benz.

2 SEATERS—JN'S $650.00 UP
Mercedes, Isotta or Hiso Standards $2500.00

NEW AVROS—$1250.00 to $1500.00
Single Seater—45 Anzani—80 Le Rhone
$450.00—$650.00

3 SEATER M.F. BOATS—HISPANO—$2000.

ALL PLANES EXCEPT SINGLE SEATER AND JNS NEW

What is a DH-6? It is an English training plane built for OX-5 motor. Span 36 ft., chord 6 ft., surface 416 sq. ft. Lands 30-35 m.p.h. and climbs 2000 ft. in 5½ minutes, loaded. We remodel them making two cockpits instead of one long one, install a new gas system and use forward stagger instead of back stagger, giving the ship a much better performance and appearance. It has about twice the factor of safety of a Canuck, lands 10 to 15 mi. slower than a JN, is more stable and easier to fly than a Standard J1 and will get in and out of even smaller places than an Avro. It has no equal for barnstorming, instruction or general passenger work. Plenty of spares—cheap.

Our ships and prices must be right. 37 of 4 different makes sold since Jan. 1st., 1922.

DEALERS—Let's get together. We will work with you.

L O O K !

MARVIN A. NORTHROP OFFERS

New JN4Ds, less motor, otherwise complete	$ 525.00
New Standard J1s, less motor, otherwise complete	575.00
Complete new sets Standard J1 wings, wires, struts, cables, tail unit, ailerons and center sections, less than $200.00. Write for price.	
Thomas Morse Scout, complete; motor, everything ..	450.00
Three passenger Avros, Le Rhone or Clerget	1200.00
New copper tipped propellers OX5 and OXX6	20.00
New OXX6 Curtiss motors	800.00
Used OX5 Curtiss motors	150.00

Dope, linen, cotton, goggles, wheels, tires, landing gears, single panels. What do you want?

16 NEW AIRPLANES
Complete in original crates
and
3,365 Curtiss Ox-5 Engines

Are offered by the War Department for your purchase in two sealed bid ssles, bids to be opened

IN WASHINGTON, D. C.
JUNE 15 and 29, 1922
At 3 P. M. (Eastern Time)

The offerings are stored, and inspection is invited as follows:

At Buffalo, N. Y., Curtiss Elmwood Air Reserve Depot—
22 airplanes, Curtiss JN4-D, without engines or instruments; not crated. Bids opened June 15.

At Millington, Tenn., Park Field—
16 airplanes—Curtiss JN4-D, complete, in original crates.
40 engines, Curtiss, OX-5, new.
215 " " " used.
Bids opened June 15th.

At Little Rock, Ark., Air Reserve Depot—
2542 engines, Curtiss OX-5, new
568 " " " used.
Bids opened June 29.

Bids will be accepted on all or any part of the equipment offered, and no special form of bid is required. The Government reserves the right to reject any or all bids. For complete information regarding these offerings, and in transmitting bids, address:

CHIEF, MATERIAL, DISPOSAL & SALVAGE SECTION, AIR SERVICE,

Room 2624 Munitions Bldg. Washington, D. C.

CASTOR OIL ALSO TO BE OFFERED

Approximately 1,212,291 lbs. of **Castor Oil,** stored at Curtiss Elmwood Depot, Buffalo, N. Y., will be sold by sealed bids to be opened in Washington, D. C., June 16th, 3 P. M. This oil is packed in steel drums of 55 gal. capacity, and in 5-gal. cans.

MF FLYING BOATS

We have purchased from the Navy all the remaining MF Flying Boats, 57 in number.

These are new, unflown and in perfect condition.

Our prices are:

MF Flying Boat, without engine, f.o.b. Philadelphia or f.o.b. Pensacola, Fla. **$675.00**

MF Flying Boat, two seater, with 100 H. P. OXX6 motor installed, ship completely tuned up and ready for flight, f.o.b. College Point, L. I., N. Y........................ **$1700.00**

MF Flying Boat, reconverted to 3 seater, equipped with 150 or 180 H. P. Hispano, f.o.b. College Point, L. I., N. Y. Model CK-14 .... **$2900.00**

This is a **real opportunity**, probably the last of its kind.

Independence!

Be your own master, make your own income, have your own business—and that the most progressive and coming business in the world today.

Many a Curtiss pilot has paid for his JN in one week out of his profits. The most successful and active pilots in the United States have tied up with Curtiss because they know the Curtiss characteristics—

RELIABILITY
STRENGTH
PERFORMANCE
ECONOMY
COMFORT

When you do business with Curtiss you are doing business with the biggest and most successful aeronautical organization in America.

Distribution centers and representatives all over the continent mean quick and efficient service; our new sales policy looks out for your interests.

If you want independence and success, get in touch with us at once.

Sea and Air Power

MR. ARCHIBALD HURD states the case in the manner of a partisan when he says in an article upon sea power and air power in *The Fortnightly Review* that "this country (England) is being challenged to prepare to confront entirely novel conditions of life; the ship of commerce, like the ship of war, is to disappear, and we are to receive the greater part of our food as well as the raw materials for our factories by aeroplane or airship, and are to conduct our export trade by the same means." That is going too far in reflecting the opinions of the aircraft advocates. Mr. Hurd is as little disposed as the Admiralty to accept the view of Sir Percy Scott that the battleship is passing into the obsolete class. He speaks with scorn of the retired naval officers "who have little or no personal experience of war and even less of commerce who have been throwing up their hats in enthusiastic support of this conception of an island country without ships of war or ships of commerce." Admiral Sir Percy Scott, by the way, is a retired naval officer, but during the war he put London in a state of defense against aircraft attack with little, if any, practical help from the Admiralty. In a normal year Great Britain imports and exports 150,000,000 tons of goods and products. Certainly Sir Percy Scott and other believers in aircraft do not hold that Great Britain can dispense with surface ships in her ocean-borne trade. Mr. Hurd argues lamely, as well as intemperately, when he says:

"There are nearly 4,000 large unarmed and, for the most part, slow merchant ships under the British flag. Is it imagined that an enemy desiring to strike this country a vital blow would devote attention to the few swift and powerfully armed men-of-war, when so many more desirable targets, in tbe shape of merchant ships and their cargoes, were presented to attack?"

In the first place, this is to assume that international law will never again be observed in warfare; and in the second place, it is to lose sight of the fact that Great Britain already possesses a strong aircraft arm for offense and defense, and will continually add to it. Should an enemy copy in the air the methods of warfare the Germans practiced under the sea, Great Britain would be well prepared. She is giving a great deal of attention to the development of aircraft.

We are told that "it is today the considered opinion both of the Naval Staff and the Board of Admiralty that defense against aircraft, so far as capital ships are concerned, is, and will keep, fully abreast of attack, whether by aircraft or submarines." But the Admiralty is far from infallible. When the war with Germany came it underestimated the potentialities of the submarine; it had little faith in the aeroplane as a fleet auxiliary; it was satisfied with the construction of capital ships that proved defective at Jutland; the shells used were not as damaging as the enemy's, and the machinery of gun elevation on the British fleet was not uniformly serviceable. Really the Admiralty is not a satisfactory authority upon defense against aircraft. Between the Admiralty and the Air Ministry there is a chronic feud.

Mr. Hurd summarizes the report of the Committee of Imperial Defense when he says: "It was held that in aircraft resided great possibilities of development, but that, in spite of the aeroplane, the airship and the submarine, the battleship, and therefore other types of men-of-war, remained practically unchallenged." "Practically unchallenged" is an unfortunate expression. Not only Sir Percy Scott but our own Admiral Sims maintains that the aeroplane successfully challenges the effectiveness of the surface warship.

It is true that the American Joint Army and Navy Board reported that "the battleship is still the backbone of the fleet and the bulwark of the nation's sea defense, and will so remain so long as the safe navigation of the sea for purposes of trade or transportation is vital to success in war." But at the same time the Joint Board also pronounced this judgment: 'The aviation and ordnance experiments conducted with the ex-German vessels as targets have proved that it has become imperative as a matter of national defense to provide for the maximum possible development of aviation in both the Army and Navy." Mr. Hurd is more impressed by the primacy given to the battleship than to the apprehension that the airship has alarming potentialities. None, however, but extremists who give free rein to their imaginations think that there can be a one-standard fleet operating only from the air, nor that surface cargo-carriers are obsolescent, soon to be succeeded by argosies of heavily freighted flying ships. As well maintain that railroads cars are to be scrapped, and the tracks torn up or abandoned to the elements. So long as the Seven Seas wash the shores of the world there will be ships of war and ships of commerce, and on land most of the carrying business will be done by the railroads and the motor car. Cost alone will limit the use of the airship in trade.—*Editorial in N. Y. Times.*

The News of the Week

Pulitzer Trophy Spurs Army Airmen

Dayton.—The United States Army Air Service will make a determined effort to win the Pulitzer Trophy in the international air race to be held at Detroit on September 15.

Announcement was made May 25 that orders had been placed for six special speed planes to be entered in this tournament. In addition, the Verville-Packard plane, winner of the 1920 classic, will be entered.

The contracts for the six speed planes were let to the Thomas Morse, Curtiss and Loening aeroplane manufacturing companies. Their construction will be rushed and they will be taken to Detroit on completion for final flight tests. Structural tests will be made at the different plants.

Major T. H. Bane, Commandant of the Engineering Division of the Army Air Service at McCook Field, said the provisions called for a guaranteed speed of approximately 200 miles an hour and what other equipment can be included in the construction to make the ships formidable contenders in the race. Contracts were drawn by the officers at McCook Field. The McCook Field entry has been undergoing a general overhauling, under the personal supervision of Alfred Verville, its designer. When this ship won the 1920 race it attained a speed of 186.7 miles an hour and was not operated at full speed. It was piloted by Lieut. C. C. Mosely of McCook Field.

Paris-London Aeroplane Falls Into Channel

A French aeroplane flying from the air station at Croydon, near London, bound for Paris, fell into the English Channel June 3. The pilot and two passengers were drowned. A cross Channel boat picked up two bodies. The accident occurred three miles from the English coast. It was observed from a Channel boat crowded with Whitsuntide holiday makers, which proceeded to a spot where the aeroplane fell.

The passengers were Gordon Ley, an Englishman, and Paul Carroll, a Paris business man. The British machine on which the two passengers had booked for the flight to Paris was not ready when they arrived at the Croydon airdrome this morning and they therefore were transferred to the French machine. Carroll's brother refused to make the flight.

Tennessee National Guard Squadron Gets Into Action

"All things come to him who waits" fittingly describes the 136th Squadron, Observation, Tennessee National Guard, which was Federally recognized in December, 1921. For many weeks the squadron "carried on" under very adverse conditions. Finally, a consignment of four JN6H's arrived, and immediate action was started to set them up the week following the completion of the first steel hangar. In the meantime the second hangar was completed, and the four H's have been set up, but lack of tools prevented the installation of motors.

Through the kindness of Major Roy S. Brown, a DH was loaned to the Regular Army Instructor, and on May 7th he flew it up to Nashville from Montgomery, bringing the necessary tools. He was accompanied by a mechanic, Staff Sergeant Baehre, of the 22nd Squadron Observation. The plane was flown back on May 10th, and in the near future a DH will be permanently assigned to the Instructor.

Much difficulty has been experienced in obtaining equipment and supplies, due chiefly to lack of funds for freight and express charges. The transportation problem has been relieved through the kind and generous cooperation of the Commanding Officer at the Old Hickory (the former government powder plant), the Ordnance Depot, and the Tennessee State Highway Department.

The State has erected on the field an administration building, containing an office, orderly room, armament room, operations room, supply room, and a small medical clinic. Needless to say, it has been of great value since its completion.

On March 28, 1922, Lieutenant Vincent J. Meloy, Air Service, formerly commanding officer of the 8th Squadron (Attack), reported to the Adjutant General's Office, and shortly thereafter the squadron launched forth into its first training schedule. For the officers it consisted mainly of classes in Infantry Drill Regulations, Field Service Regulations, Manual of Courts Martial and some practical work witb the D-R system of signalling. The enlisted personnel were given lengthy periods on the school of the soldier, squad and company, and practical work on rigging and motors.

The field is situated on the Lebanon Pike, adjoining the Hermitage, the home of Andrew Jackson. It is about 12 miles northeast of Nashville and about two miles south of Old Hickory. The hangars and administration building border the south side of the field, which is approximately 2200 feet square, with good approaches on all sides. A white circle, 50 feet in diameter, marks the center of the field.

Much credit is due Major J. C. Bennett, Jr., Air Service, Tennessee National Guard, the officers and enlisted men of the squadron, Major Baxter Sweeney, former Adjutant General, and Brigadier General P. I. Brumit, the present Adjutant General, for their perseverance, hard work and untiring efforts in getting the 136th under way. A word of praise is also due the Nashville Commercial Club for their efforts in behalf of the squadron.

World Flyers' Plane Smashed at Marseilles

Marseilles.—Major W. T. Blake was compelled to make a forced landing at Borely Park, just outside Marseilles, May 28, while on a flight from Lyons to Turin, Italy, in the continuation of his attempt to fly around the world.

The machine struck on rough ground, damaging the running gear and smashing the propeller. It is being towed to the Miramis aviation field for repairs and the flight probably will be delayed for several days. Neither Major Blake nor his companions, Broome and MacMillan, was injured.

Air Bomber Hits Target Three Times at 3,000 Ft.

Lieutenant Victor E. Bertrandas hit the Rock-and-Rye at an altitude of 3,000 feet three times running May 30, in a demonstration of aeroplane bombing at Mitchell Field, Long Island. He was not unduly elated when he descended, however, for Rock-and-Rye was the name given to a warship model of wood and canvas, twenty-five feet long, which served as a target.

At 2,500 feet Lieutenant Bertrandas missed the Rock-and-Rye by 100 feet. He mounted to the 3,000-foot level and dropped five more bombs, the first three of which landed fairly on the target, which burst into flames. A brisk wind was blowing at the time. Lieutenant L. V. Bean was pilot.

There was a ten-mile relay race at the army held also, in which each contestant used two aeroplanes and made the trip from the first to the second in a wheelbarrow. Lieutenant F. C. Fishback won. Captain I. S. Eaker won another ten-mile aeroplane race.

Plane Wins 105-Mile Race Against Stork

Norfolk, Va.—An aeroplane, fitted out like an ambulance, won a race with the stork May 30. It was a 105-mile race. The patient was landed safely at the door of the Public Health Hospital in this city and at last reports was doing well.

Mrs. W. N. Wilds, wife of a coast guard at Chicomico, N. C., was the patient. She stood the air trip well and was attended by the doctors during the entire flight.

Urgent calls for a doctor were sent out from the Hatteras radio station to the coast guard division headquarters today. No doctor for Mrs. Wilds could be procured in the little coast guard settlement at Hatteras.

Captain D. F. A. Deeote, coast guard division commander here, ordered a plane and doctor from the naval base. Dr. Engel was routed from bed and the plane, one of the fastest at the base, departed for the coast guard station. The stork was expected this morning and the local doctor, who had promised to come, telegraphed from twenty miles away that impassable roads would keep him from arriving at Mrs. Wilds's bedside.

Aero Club of El Paso

Unusual interest is being displayed by former officers of the Air Service in the organization of the Air Service of the 90th Division Organized Reserves of which El Paso is the headquarters.

For some few months the former army air service men have been getting together at a weekly noon luncheon as well as at other get-togethers for the purpose of bringing out the "T."

Just recently Lieut. Morris has been assigned to El Paso for the purpose of organizing the air service reserves and almost without exception the men have signed up for reserve commissions.

Not a small amount of flying talent is represented by our club. We have many overseas men and three of our members were members of that famous Kosciuszko squadron which was so effective with the Polish army against the Bolshevists. These men are Earl F. Evans, E. W. Chess and Bob Slaughter.

The AIRCRAFT TRADE REVIEW

Rickenbacker on 15,000-Mile Air Tour

Just as we go to press announcement is made of what is termed the longest flying venture ever planned from Mitchel Field, near Garden City, L. I., when Edward V. Rickenbacker, during the war America's premier ace and at present an official of the Rickenbacker Motor Company, and three companions will set out on an aerial industrial survey of the United States. In three months of constant travel over almost every State in the Union, Rickenbacker will stop at sixty-six of the more important cities of the nation.

On the completion of the flight, which is scheduled to end in Detroit, Mich., about September 1, Mr. Rickenbacker will forward to Major General Mason Patrick, Chief of the United States Air Service, a report on aeronautical conditions viewed from the angle of reserve national defense throughout the country. This report will be supplemented with information regarding emergency and permanent landing fields, meteorological conditions and the status of public interest in flying.

Mr. Rickenbacker said he had accepted invitations to address various organizations on aviation in cities where stops are to be made. He estimated it would be necessary to travel eight months by rail and motor to accomplish the survey he contemplated completing in three months.

"We can do a month's traveling in less than a week by plane," he said. "We plan to spend every night in a hotel instead of bumping along over the rails in a Pullman berth. The information we will seek has long been needed."

Accompanying Mr. Rickenbacker will be Edward Stinson and Lloyd Bertand, two of the leading flyers of this country, and Steve Hannigan, a writer, who will act as historian of the trip. The first leg of the flight will be from New York to Detroit, where the party will stop over night and "hop" to Chicago on Wednesday. The flyers will travel in a Junker all-metal monoplane equipped with a 185-horsepower BMW motor. The passenger cabin is entirely enclosed and fitted with electric lights and other conveniences.

In connection with the proposed trip of Rickenbacker the Aeronautical Chamber of Commerce yesterday gave out a statement based on a report submitted to the Secretary of Commerce that 3,000,000 miles in cross-country flights without a fatality was the safety record of aviation in this country for 1921.

In signed statements, 125 operators in all parts of the United States having an equipment of 600 planes showed that in twelve months they had made 130,736 flights, carrying 122,512 passengers 2,907,245 miles. Including the flights made by "gypsy" pilots the Aeronautical Chamber of Commerce fixed the number of miles flown at 3,000,000.

Aerial Advertising

A novel newspaper advertising stunt has been attracting London crowds and giving them the aviation neck as they watched an aeroplane high in the sky write with a stream of white smoke the letters "Daily Mail." The stunt was first tried on Derby day when betting on the big race was active.

The machine was easily 10,000 feet in the air, where there was no wind. When the word "Daily" had been written and the aviator was maneuvering to begin a new word the bookies asked what odds people would lay as to which one of half a dozen newspapers would be named. The smoke hung against the blue background and the letters were distinct for some time. The plane carried a smoke generator and powerful ejector, which forced jets of smoke in the trail of the machine as it climbed up and down in the air. It was estimated the space occupied by "Daily Mail" in the sky was more than three miles wide.

The Decay of a Simple Eddy

This report (No. 144) by H. Bateman of the National Advisory Committee for Aeronautics, deals with a generalization of Taylor's formula for a simple eddy. The discussion of the properties of the eddy indicates that there is a slight analogy between the theory of eddies in a viscuous fluid and the quantum theory of radiation. Another exact solution of the equations of motion of a viscuous fluid yields a result which reminds one of the well-known condition for instability in the case of a horizontally stratified atmosphere.

A copy of Report No. 144 may be obtained upon request from the National Advisory Committee for Aeronautics, Washington, D. C.

Prest's Plane Damaged

Cheyenne.—C. O. Prest, aviator, attempting to fly from Buffalo to Siberia, was unable to continue his flight from this city May 29 because of damage done to the wings of his airplane by a hailstorm the day before.

Carlstrom Field to Be Closed

Tampa, Fla.—Uncle Sam has finally decided to abandon the Carlstrom aviation field at Arcadia, Fla., as soon as the cadet class, which is now in training there, is graduated, it has just been announced by Maj.-Gen. M. M. Patrick, chief of the army air service, who has completed an inspection of the field.

An announcement that the war department would transfer the field's training activities to a Texas camp was made some time ago, but vigorous protests from all parts of Florida arose and the matter was given more thorough consideration.

General Patrick stated that there was no fault to be found with the flying conditions at Carlstrom and that the field had done a great work for the army, but it is a part of the pressure of economy to close numbers of aviation fields. The fields which are to be retained, most of them being in Texas, are equipped with greater housing facilities than is Carlstrom. The date of abandonment has been set for some time in June.

COMING AERONAUTICAL EVENTS

AMERICAN

Sept. 4.—Detroit Aerial Water (*about*) Derby, Detroit. (Curtiss Marine Flying Trophy Competition.)

Sept. 15.—Detroit Aerial Derby, (*about*) Detroit. (Pulitzer Trophy Race.)

Sept. 30.—First Annual Interservice Championship Meet. (In preparation.)

FOREIGN

Aug. 1.—Coupe Jacques Schneider. (*about*) (Seaplane speed race.) Italy, probably Venice.

Aug. 6.—Gordon Bennett Balloon Race, Geneva, Switzerland.

Oct. 1.—Coupe Henri Deutsch de la Meurthe. (Aeroplane speed race.) France. American elimination trials, if required, to be held about Aug. 15, at Mitchel Field, L. I.

REGULATION OF AIR TRAFFIC

By DEVALUEZ*

CONSIDERING the progress of aerial navigation, the importance of uniform laws and the necessity of establishing certain principles and regulations intended to avoid controversies, and animated with the desire of aiding the development of international aerial communications for the purposes of peace, on October 13, 1919, the signatory governments of the peace treaty established a convention regulating aerial navigation.

The high contracting parties, while recognizing the complete and exclusive sovereignty of each power over the air space above its own territory, studied all cases susceptible of creating litigation between the different governments due to international aerial navigation and established laws accordingly.

With the observation of these laws, each government contracted to accord, in times of peace, to the aircraft of the other signatory powers of the convention, the liberty of inoffensive passage over its territory.

Without awaiting the signing of the protocol of this convention, most of the countries made special agreements with the countries to which they were joined by air routes and published special rules regulating the circulation of their aircraft over their own territory.

Thus France made agreements with Great Britain, Switzerland and Holland, and a decree was signed July 8, 1920, regulating aerial navigation in France. This decree, together with the bill subsequently submitted to the Senate, inspired the international convention and differed from the latter only in certain details.

It appears, therefore, that we can study concurrently the regulations for international aerial traffic established by the convention of October 13, 1919, and the French regulations established by the decree of July 8, 1920. These two sets of regulations supplement each other, the second being the practical application of the principles contained in the first.

The principal questions covered by the present legislation are as follows:

1. Conditions of safety which must be fulfilled by aircraft.
2. Licenses for members of the crew.
3. Traffic rules to be observed by French and foreign aircraft.

To these regulations there must be added those connected with the customs laws and the measures adopted by each country for its national defense.

Such are the broad lines of aerial regulation, which will be briefly expounded in the present article, some of these questions, moreover, needing to be the subjects of special communication.

Safety Requirements of Aircraft

Both international and French legislation require that no aircraft shall be operated without a certificate of navigability. This certificate, as defined by the French decree, is the attestation of the safety characteristics of the aircraft.

For the purpose of requiring guaranties as regards the safety characteristics of an aeroplane used for commercial purposes or for air travel, the French regulations impose a series of tests for new aircraft types and supervision of quantity production of aircraft.

The following procedure has been adopted and seems capable of giving all the necessary guaranties. The builder of a new type of aircraft must present his machine to the Technical Section of Aeronautics, which will subject it to static and flight tests. These tests will show whether the aircraft has a large enough factor of safety and whether its characteristics and performances fulfill the requirements of the use for which it is designed.

After the tests have been made on the sample aircraft its quantity production is supervised by the Section of Aeronautic Construction, which makes sure that the aircraft thus produced is an exact copy of the sample, both in its characteristics and in the nature of the materials employed in its construction. In quantity production any aircraft that has undergone modifications susceptible of affecting its characteristics and performances must be subjected to the same tests as the original sample.

After the tests of a new type have been completed and adjudged satisfactory, its construction being under the control of competent parties, the aircraft may receive its certificate of navigability, and as soon as it is employed it comes under the control of the Aerial Navigation Section.

This section determines, at longer or shorter intervals, according to the use made of the aircraft, whether it continues to meet the safety requirements for holding the certificate of navigability. According to circumstances, the certificate is continued if the aircraft is in proper condition, or suspended if it is temporarily unavailable on account of undergoing repairs, or permanently withdrawn, if it is unfit for further use.

An aircraft, on receiving its certificate of navigability, also receives its books, consisting of a route book, an aircraft book and an engine book. These books, which must be kept strictly up to date, render it possible to control the use of the aircraft, to comment on the routes followed and to keep track of incidents of navigation, accidents and repairs made.

Licenses

In order to take his place as an authorized member of the crew of a public aircraft for transportation or touring, any person performing the functions of pilot, navigator or mechanic must have a license or certificate. These certificates, which attest his physical and technical qualifications, comprise:

1. License as touring pilot, which does not confer the right to serve on a public aircraft, no matter in what manner he may be remunerated.

2. License as public transportation pilot, which gives him the right to carry passengers or freight for pay.

In each of these two classes (touring and public transportation) there is a special license for pilots of naval aeroplanes and seaplanes, by reason of special qualifications considered desirable for piloting such aircraft.

3. License as pilot of free balloon.

4. Three licenses (first, second and third class) as airship pilot. The holder of a license of the first class can command all kinds of airships. The holder of a second class license may command airships of less than 20,000 cubic meters gas capacity. A holder of a third class license may command airships of less than 6,000 cubic meters.

5. There are two aerial navigator licenses, elementary and superior. The presence of an elementary navigator is required by day on every public transportation aircraft making a trip of more than 200 and less than 500 km. over land, or a trip of less than 200 km. over water and such that the course, supposedly straight, does not carry the airship over 50 km. from the coast. By night the presence of an elementary navigator is required for every trip of less than 100 km. without leaving the country.

The presence of a navigator holding a superior license is required on any public transportation aircraft making voyages, by day or night, above land or water for distances greater than those mentioned above.

6. Only one form of license for mechanics employed on public transportation aircraft.

Candidates for the various licenses must undergo practical tests and pass technical examinations in accordance with a methodical plan and corresponding to the requirements of the aerial tasks which they propose to perform. Military pilots who have kept in practice may be excused from the flight tests.

With the exception of the license of touring pilot, licenses are only granted candidates, after satisfactorily passing a medical examination before a special board of physicians.

All licenses must be renewed every six months. In order to have his license renewed, the holder must submit to another medical examination. If he is an aeroplane pilot he must show by the record of his aerial services during the previous six months that he has lost none of the professional qualities required for the issuance of his license.

The interval of time during which the holder of a license must not have interrupted his aerial services is six months for aeroplane pilots, two years for airship pilots and five years for navigators.

Traffic Rules for Aircraft Regulation

We have just seen that an aircraft cannot be certified for flying without answering certain rigid requirements and that similar precautions are taken with regard to the crew.

To these fundamental conditions, which are mostly for increasing the safety of aviation, there have just been added rules for preventing collisions in flight, especially over and in the vicinity of airdromes.

The limits of this article do not allow us to explain in detail the measures adopted for this purpose. We will mention, how-

* From "Premier Congrès International de la Navigation Aérienne." Paris, November, 1921, Vol. I, pp. 165-170.

Digitized by Google

ever, that these very complete regulations anticipate the maneuvers to be made by aircraft crossing or passing one another and landing or taking off simultaneously. They also provide for flight in the vicinity of and above airdromes: the direction aircraft must turn in response to signals and according to an established code; the interdiction of all acrobatic maneuvers and the division of the airdromes into landing and departing zones and a neutral zone.

These rules also prohibit flight over cities and towns, save at altitudes from which an aircraft can land outside the town, in case of failure of its means of propulsion.

For the purpose of being able to control the circulation of aircraft and identify them in case of infractions of traffic regulations, registration rules have been established. Every aircraft must be recorded in a special register and receive a registration certificate, on which are mentioned the distinguishing marks assigned to it, together with the name and address of its owner.

The registration marks, which consist of a letter indicating the nationality and a group of four letters, must be painted on the aircraft at designated locations and large enough to be ordinarily easily read by an observer on the ground.

Customs Regulations

In order to conform to customs laws, the following regulations have been adopted. Aircraft leaving the country can only depart from airdromes specially designated by the Customs Department of each country. Those coming from other countries must land on the same airdromes. Moreover, all aircraft flying from one country into another must cross the frontier between certain designated points.

The observation of these conditions enables the accomplishment of the customs formalities and the surveillance of the points of passage. Customs formalities on the designated airdromes comprise the verification of the freight, endorsement of manifest and route book and collection of customs duties.

Chance landings outside customs airdromes are provided for. If the commander of an aircraft, leaving a customs airdrome for a foreign country, lands before reaching the airdrome where he should accomplish the customs formalities, he must have his cargo verified by the nearest representative of the Customs Department. He may depart again only by authorization of this department, which, after verifying his books, designates the airdrome where the next landing is to be made for the purpose of paying the customs duties.

Safeguarding the National Defense

By the terms of the international convention the contracting countries having reserved the right to prohibit, for military reasons, flight over certain portions of their territory, each country has published special regulations on this subject.

France, who, by the decree of July 8, 1920, had anticipated the prohibition of flight over certain portions of her territory which she reserved the right to designate later, abrogated these dispositions by the decreee of June 10, 1921.

Private French aircraft and the aircraft of countries with which France has made agreements are therefore authorized to fly over all parts of the country, on condition that they observe the air traffic regulations given above.

Flight over certain zones is, however, forbidden all aircraft carrying photograph or kinetograph cameras.* Special authorization may be accorded French citizens to use photograph cameras over the forbidden zones, but this privilege cannot be extended to foreigners.

Outside the prohibited zones, any French subject may use photograph cameras without special permission. The same privilege may be accorded foreigners, but only after a request has been addressed, by the parties interested, to the "Service de la Navigation Aerienne" (Department of Aerial Navigation), and after inquiry of the department concerned (Department of the Interior or of Foreign Affairs), according to whether the foreigner resides in France or not. Permits for the use of photograph cameras by strangers are temporary and their validity cannot exceed one month.

The above brief exposition of aerial regulations now in force does not pretend to be exhaustive, but only a summary of legislation which is entirely new and of recent application.

This legislation, in harmony with the present resources and needs of aerial navigation, cannot be considered final and must be modified in the future according to conditions.

It may be affirmed that safety must depend on the strict application of such regulations and without safety there can be no great development of aerial navigation.

(Translated by the National Advisory Committee for Aeronautics.)

* (a) The part of France east of a line passing through the valley of the Meuse, the valley of the Moselle and the upper course of the Doubs as far as Switzerland.

(b) The six military ports of Cherbourg, Brest, Lorient, Rochefort, Toulon and Bizerte, as also Dunkerque, Nice, Villefranche and Bonifacio.

THE LARSON TENSIOMETER

IN aeroplane construction the minimum weight which is consistent with safety is essential. This requires that the stresses to which the parts of the structure are subjected be kept as low as possible. Some parts of the machine are subjected not only to the stresses imposed on them by the aerodynamic or flying load but also to internal stresses due to the tension in the stay and drift wires. A certain amount of tension in these wires is necessary to maintain the alignment of the machine. Any excess tension will increase the initial stresses in the structure and thereby either reduce the factor of safety or require a heavier construction. Cases are on record in which improper adjustment in the drift wires resulted in the failure of wing members. Also when two or more wires are used to carry a load it is important to know that each receives its share of the tension. Some method of accurately determining the tension in a wire or cable is therefore desirable and it is for this purpose that the Larson Tensiometer has been designed.

The tensiometer consists essentially of a frame about 10 inches in length with two supports, a fixed distance apart, between which the wire may be adjusted. (See photograph.) Midway between these supports and operated by hand levers is a plunger which deflects the wire from its normal position. The operation of deflecting the wire compresses a calibrated spring. A dial indicator, called the load dial, measures the compression of the spring, and this indicates the tension in the wire. A second dial indicates the deflection of the wire to the nearest 0.001 inch.

The theory upon which the instrument is based is simple. If a wire, under tensile stress, is deflected from a straight line a system of three concurrent forces, consisting of the tensions in the two segments of the wire on either side of the deflecting force and the lateral force, is formed. The system is in equilibrium and if the directions of all the forces and the magnitude of one are known the magnitude of the other two can be found.

In the operation of the instrument the wire is deflected a certain prescribed amount, hence the angles between the forces will be constant and the deflecting force will be proportional to the tension in the wire. The instrument is made direct reading by graduating the load dial so as to read the tension in the wire instead of the compression in the plunger spring. The sensitiveness of the instrument depends upon the sensitiveness of the load and deflection dials. Operating with a deflection of 0.1 inch, the deflection can be read directly to 0.001 inch, or 1 per cent. The load dial reads directly to the nearest 10 lbs.

To obtain the highest degree of accuracy on some of the larger sizes of wire the readings must be corrected for two reasons: (1) The tension in the wire is slightly increased when it is deflected from a straight line, (2) the wire offers a resistance to deflection because of its stiffness as a beam. Both of these tend to make the indicated load too large, but the corrections are of such a nature that they can be readily made when constant deflection is used.

The increase in stress due to deflecting the wire from a straight line depends upon the sectional area and the length of the wire, and upon the rigidity of the supports to which the wire is attached. Using the standard deflection, and assuming the supports to be rigid, it may be expressed by the formula

$$p = \frac{60{,}000}{L} A,$$ in which p is the increase in total load in pounds. A is the area of the wire in square inches and L is the length of the wire. It will be seen that this increase is small for conditions met in practice. Furthermore, this formula is based on the assumption that the ends are held in rigid supports. Any yielding of the structure to which the wire is attached will reduce the effect so that for aeroplane purposes this correction can generally be neglected.

The increase in the indicated load caused by the stiffness or beam action of the wire depends upon the amount of end restraint at the supports of the instrument and upon the section modulus of the wire. The end restraint depends upon the tensile

Digitized by Google

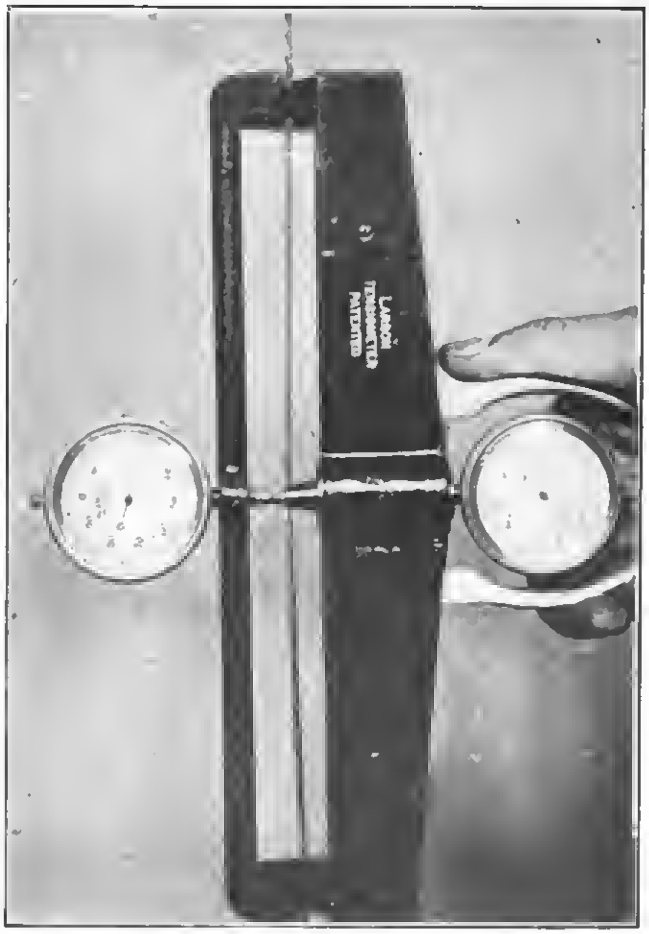
load on the wire. With no load the wire acts as a simple beam and as the tension on the wire increases the action approaches that of a fixed ended beam. The section modulus of the flexible cables is an uncertain factor, hence a theoretical consideration of this problem is impracticable. The only satisfactory method of determining the proper corrections is to calibrate the instrument on the various sizes of wire and cable upon which it is to be used. Calibration curves are available for most sizes of wire, both circular and streamline, and for all sizes of cable in use on aeroplanes.

As found from these curves the corrections for all cables up to 1/8 inch are negligible. For cables from 5/32 inch to 1/4 inch and for all sizes of round solid wires the corrections vary with the size of cable or wire, but not with the tension in the wire for loads above 200 lbs. For cables above 1/4 inch the corrections vary slightly with the load as well as with the diameter of the wire if the standard 10-inch instrument is used. A longer instrument on these large sizes of cable would materially reduce the corrections necessary.

Although corrections are required on a number of the sizes of wire and cable in use in aeroplanes the instruments can be made direct reading by setting the load dial for the correction of the size wire or cable upon which the observation is being made. The dial readings will then indicate the actual load on the wire near enough for all practical purposes. A plate giving the dial settings for the various sizes of wire is attached to the instrument.

The instruments have also been used in connection with sand loading test son planes and other research work. For such work in which greater accuracy is desired the calibration curves may be used to determine the load corresponding to any given reading.

In operation the instrument is never attached to the wire. It is simply placed in position, as shown in the photograph, and the hand levers brought together until the deflection dial makes one complete revolution (0.1). The reading on the load dial will then be the tension in the wire. When using the instrument on wires or cables for which corrections are required the load dial is adjusted by turning the face to the proper *zero* for the particular size of wire. The actual tension in the wire is then read on the load dial in the same manner as if no correction were needed. The time required to take a reading is only a few seconds, so that a complete set of readings on a plane may be taken in a very short time.



The Laraon Tenalometer

PROPOSED AIR TRAFFIC LAW

By PROF. GEORGES RIPERT,

Of the Paris College of Law and the School of Political Science[1]

SCIENTIFIC experiments and sporting activities have been followed by commercial exploitation. The important cities of Europe are connected by regular aerial navigation service. The "Indicateur Aerien" gives the time schedules, the transportation rates and the conditions for the acceptance of merchandise shipments. But when all these aircraft have left the ground, what law is going to control them, their crews and their passengers in this new domain which human intelligence has conquered?

Let us not imagine that, in overcoming the physical laws which seemed to hold him to the ground, man can thus easily evade juridical laws. The law of the country does not abandon him in these ethereal spaces, for every country has extended its frontiers to the sky and claims "complete and exclusive sovereignty over the atmospheric space above its territory.[2]

Moreover, the flights are of short duration and every time the aviator renews contact with the ground he returns to the juridical community which, for the moment, he may have thought he had left.

It is just because it cannot escape the law that aviation demands its due. It has today only an administrative set of regulations[3] and the subsidies accorded by the government[4] There is no aviation code of law.

It is a curious fact, however, that international law has here preceded the elaboration of internal law. An international convention signed October 13, 1919.[5] by the representatives of 32 countries "animated with the desire to aid the development of international aerial communications for peace purposes"[6] has established general rules relating to the nationality of aircraft and to the admission of aircraft over foreign territory. It created an international air traffic commission.[7] Annexes to the convention regulated air traffic in detail.

It would be very illogical, now there is an international convention, not to have an internal law. Hence, the government took the initiative on March 25, 1920, in introducing a bill on

[1] From "Premier Congrès International de la Navigation Aérienne," Paris, November, 1921, Vol. I, pp. 171-179.
This bill has been referred to the "Commission de la Société d'Etudes législatives" (Committee of the Society for Legislative Research), composed as follows: Mr. Fabry, counselor to the Court of Cassation, president; Messrs. Dufourmantelle, Imbrecq, Henri Fabry, Léon Jacob, Mantin, Pierrot, Rolland, Lumien, Talamon; Mr. Georges Ripert, chairman and Mr. René Capitant, secretary.

[2] International convention of October 13, 1919, for the regulation of aerial navigation, Art. 1: "The high contracting parties recognize that each power has complete and exclusive sovereignty over the atmospheric space above its own territory."

[3] Decree of July 8, 1920, regulating air traffic in France (Journal officiel, July 13, Bulletin de la Navigation Aérienne, No. 7). Decree of Aug. 14, 1920, fixing the conditions for the issuance of aircraft navigability certificates (Journal officiel, Aug. 14, Bulletin No. 6). Decree of April 14, 1920, establishing registration rules and the distinctive marks to be borne by aircraft (Journal officiel, Aug. 14, Bulletin No. 6). Bulletin of Aug. 26, 1920, regulating air traffic, beacons and signals (Journal officiel, Aug. 28, Bulletin No. 6). Decree of Sept. 18, 1920, relating to licenses of the navigating personnel of civil aeronautics (Journal officiel, Sept. 24, Bulletin No. 7). Decree of Sept. 30, 1920, establishing rules for keeping the books on aircraft (Journal officiel, Oct. 5, Bulletin No. 8). Decree of Jan. 12, 1921, establishing the customs rules to be observed by aircraft landing in or leaving France (Journal officiel, Jan. 18, Bulletin No. 11). Decree of June 10, 1921, regulating the transportation and use of photograph and kinetograph cameras on aircraft. Decree of June 10, 1921, repealing previous regulations relating to forbidden zones.

[4] Budget of April 30, 1921, Art. 88.

[5] The law of Jan. 29, 1921, authorized the ratification of the convention. It was completed by an additional protocol May 1, 1920, which was ratified July 15, 1921.

[6] Preamble of the convention.

[7] This commission was placed under the authority of the Society of Nations (Art. 34).

Digitized by Google

air traffic.[8] It amended this bill by a second, designed to be incorporated in the first. This bill has been examined by the commission, but I cannot say that it was a satisfactory guide, since it was both incomplete and disconnected. Though rich in penal regulations, it is very incomplete in the civil code of aviation. It would appear to threaten more than encourage.[9] On the other hand, inspired by previous decrees, it has maintained the general progress of police regulation. This bill was, however, voted by the chamber of deputies on the recommendation of Mr. Bazire, in July, 1921. Foreign legislation does not yet offer any satisfactory model.[10] In most countries, the rules adopted are simple administrative measures relating to air traffic and chiefly copies of the measures of the international convention. The decree of the Swiss federal council of January 27, 1920, however, contains certain remarkable provisions.

It is therefore necessary to draw up (without the authority of tradition nor the example of a foreign law) a law suited to the new form of commercial exploitation. This is all the more difficult, because a good law must not only satisfy the requirements of the time, but also make suitable provision for the future development of aviation. When we search in the juridical world for laws which may serve us as a basis, we are immediately led to think of maritime law.

The words themselves suggest the comparison. The vehicle bears the name of aircraft and its flights are called aerial navigation. These words are no misnomers. Like the ship, the aircraft has an individuality and a nationality of its own. It carries with it a small colony of pilots and passengers. It constitutes the territory of a small community. The one who guides it must have special rights and duties. He is not only an officer, but also a chief. The aircraft, its crew, its passengers and freight run a common risk which may prove dangerous for them and others. All these conditions are the very ones which have created maritime laws.

There is, however, a difference, which cannot be disregarded. Sea and land are in some sort on the same plan and the ship never leaves its element. The aircraft flies above the ground and there are people and property on the ground. Thus there are two juridical worlds superposed. On the other hand, an aircraft returns to the ground and there becomes an inert or rolling vehicle. Instead of comparing it with a ship, would it not therefore be fairer to liken it to an automobile and subject it to terrestrial laws, since, after flight, it comes back to rest and renew its strength on the ground?

I do not think that such a conception could give aviation the law it requires. In my opinion, only a constant comparison with maritime law, with necessary modifications, can make it possible to state and solve the problems. Naturally, we must not expect to copy an aerial law from a maritime law, which has been elaborated by long centuries of work and which is enacted for a perfect system of navigation. But there was a time when maritime voyages were only made along the coast and when boats were pulled up on dry land after their return to port. At that time the whole maritime law consisted of but a few very simple rules. Such is the aircraft of today, which returns to earth after a short flight and such are the present aerial laws, taking into consideration the progress of juridicial science. Soon aircraft will remain in the air for days at a time and will make distant voyages. Then aerial laws will be improved and will presumably become more and more like maritime laws.

PART I.[12]

Aircraft

Chap. 1. General Provisions

Art. 1. The present law applies to all machines capable of lifting themselves or circulating in the air (Pr. Art. 2).

Art. 2. Military and government aircraft, exclusively assigned to public service, are only subject to the laws relating to the responsibility of the proprietor or the exploiter (Pr. Art. 2; Conv. Art. 30 and 31).

Art. 3. Every aircraft must be entered in a register, kept by the department in charge of the air service. It is distinguished by a name or number and by the designation of the class to which it belongs (Pr. Art. 3; Conv. Art. 10). A decree will designate the classes of aircraft which are not required to register (Pr. Art. 9).

Chap. 2. Nationality of Aircraft

Art. 4. An aircraft entered in the French register has the French nationality and must carry symbol of this nationality according to regulations (Pr. Art. 1 and 3; Conv. Art. 6 and 10).

Art. 5. No aircraft can be registered in France unless it belongs entirely to Frenchmen (Pr. Art. 2; Conv. 7, par. 1).

Only French companies can be registered as the proprietors of aircraft. Moreover, in partnerships, all the persons associated by name and all silent partners and, in stock companies, the president of the administrative council, the manager and at least two-thirds of the directors must be French (Pr. Art. 3; Conv. Art. 7, par. 2).

Art. 6. An aircraft registered in France loses its French nationality if the conditions of Art. 5 are not fulfilled or if its proprietor has it registered in a foreign country (Pr. Art. 3).

Art. 7. Any aircraft registered in a foreign country can be entered in the French register only after the erasure of its entry on the foreign register (Pr. Art. 3; Conv. Art. 8 and 9).

Art. 8. Aircraft of foreign nationality cannot fly over French territory unless the right is accorded them by a diplomatic convention or if they receive authorization, which must be special and temporary (Pr. Art. 1; Conv. Art. 5).

Art. 9. The commercial transportation of passengers and freight between different points on French territory and between France and the French colonies is reserved to French aircraft, with the privilege of according special and temporary concessions by decree (Conv. Art. 16 and 17).

Art. 10. The juridicial relations between passengers on a foreign aircraft in flight are governed by the law of the country of the aircraft, whenever such law is normally competent.

However, in the case of a crime committed on a foreign aircraft, French courts are competent, if the author or the victim is of French nationality, or if the aircraft lands in France after the commission of the crime (Conv. Art. 32 and 33).

Chap. 3. Ownership and Mortgaging of Aircraft

Art. 11. The register gives the name and address of the owner of the aircraft, the type of machine and its name or number.

Art. 12. Aircraft are personal property for the application of the laws of the civil code, but the cession of property must be confirmed in writing and only affects third parties by being entered in the register.

Every property transfer, by decrease or otherwise, must be recorded in the register at the request of the new proprietor.

Art. 13. Registrations are public property and any one may obtain a certified copy.

Art. 14. Aircraft may be mortgaged. The mortgage is recorded in the register. The law of July 5, 1917, on fluvial mortgages has been declared applicable to aircraft mortgages, the official who keeps the register being substituted for the registrar of the tribunal of commerce for this purpose.

Chap. 4. Seizure and Sale

Art. 15. The seizure and forced sale of an aircraft are made as provided by the law of July 5, 1917, on the registration and mortgaging of river boats, and the record of the proceedings is always entered in the register.

Art. 16. In case of seizure for infringement of a patent, the proprietor of the foreign aircraft, or his representative, may obtain a release on depositing a bond, the amount of which, in default of mutual agreement, is fixed with the least possible delay by the justice of the peace of the place of seizure (Pr. Art. 16; Conv. Art. 18).

Art. 17. When the proprietor of the aircraft is not domiciled in France, or when the aircraft is of foreign nationality, any creditor has the right to make a seizure with the authorization of the justice of the peace of the canton where the aircraft has landed. The judge may grant a withdrawal of the seizure, if the proprietor offers to deposit a bond equal to the amount of the indebtedness claimed, and he can order such withdrawal, on fixing the amount of the bond, in case of dispute over the amount of the debt (Pr. Art. 39).

Art. 18. The public authorities have the right to seize any French or foreign aircraft which does not fulfill the conditions provided by law, or of which the pilot has committed an infraction.

---

[8] The articles of this bill are referred to by the abbreviation Pr. ("projet," bill).

[9] "The original characteristic of this bill," writes Deputy Bazire in his report, "resides especially in its being a collection of penalties, which enable quick repression of law infringements."

[10] *Great Britain.*—Law of March 1, 1919, which enabled the regulation of air traffic by decree.

Belgium.—Decree of Nov. 27, 1919, supplemented by a departmental decree adopting the regulations of the international convention.

Italy.—Decree of Nov. 27, 1919.

Spain.—Decree of Nov. 5, 1919, on air traffic; decree of April 27, 1920, on rules relating to pilots, observers and mechanics of the civil air service; decree of April 17, 1920, on foreign aviators in Spain; decree of March 6, 1920, on registration of aircraft.

Switzerland.—Decree of the federal council, Jan. 27, 1920, on air traffic regulation in Switzerland.

Holland.—Decree of Sept. 7, 1920, on air traffic.

Colombia.—Decree of March 15, 1920, on the regulation of aviation.

[11] Does it not thus come under fluvial law? In countries where fluvial law is important (Belgium, Holland, Germany), river and canal transportation are governed by maritime law or rules based on this law.

[12] The abbreviation "Pr." refers to the proposed law voted by the Chamber of Deputies; "Conv." to the convention of October 13, 1919.

Digitized by Google

An aircraft can be confiscated only in cases provided by law (Pr. Art. 39).

PART II.

Air Traffic

Chap. 1. Right of Circulation

Art. 19. Aircraft may circulate freely above French territory, excepting for the reservations of Art. 8 (Conv. Art. 5).

However, the right for an aircraft to fly over property cannot be exercised under conditions such as to interfere with the rights of the proprietor.

Art. 20. Flight over certain portions of French territory may be prohibited by decree for military reasons. The location and extent of the forbidden zones must be definitely indicated by the decree.

Any aircraft which enters a forbidden zone is required, as soon as it becomes aware of the fact, to give the proper signal and land on the nearest airdrome outside the forbidden zone (Pr. Art. 10; Conv. Art. 3 and 4).

Art. 21. An aircraft may fly over a city or town only at such an altitude that it would always be possible to land outside the city or town or on a public airdrome, even if the engine should stop (Pr. Art. 20).

Art. 22. All acrobatic stunts, consisting of perilous and useless evolutions, are forbidden above cities or the part of an airdrome open to the public (Pr. Art. 20, par. 2).

Art. 23. Evolutions of aircraft for public exhibition can occur only with permission of the chief of police after consultation with the mayor.

If the test consists of a trip including several successive landings, the permission is given by the Minister of the Interior (Pr. Art. 19).

Chap. 2. Landing and Airdromes

Art. 24. Except in cases of urgent necessity, aircraft must land only on airdromes open to the public (Pr. Art. 4; Conv. Art. 24).

Art. 25. In case of landing on private property, the owner of the land cannot oppose the departure or removal of an aircraft the seizure of which has not been ordered.

Art. 26. An airdrome is any field specially prepared for the departure and landing of aircraft and designed to serve air traffic either in public or private capacity.

Art. 27. Public airdromes are created by the central government, the "departments" (counties) or the "communes" (townships).

Departmental or communal airdromes can only be established with the authorization of the minister in charge of the air service and they are subject to the surveillance of government agents (Pr. Art. 4; Conv. Art. 24).

Art. 28. Fields to be acquired for the establishment of public airdromes may be the object of a declaration of public utility by decrees rendered in the form of public administrative regulations (Pr. Art. 41).

Art. 29. An airdrome may be established by the owner of the field only by administrative permission.

The permit may specify that the airdrome must be open to all aircraft, in which case it will fix the rent to be paid the owner of the land. The permit may be withdrawn, if the conditions are not observed (Pr. Art. 4).

Art. 30. Aircraft which cover international routes must take off from and land on special airdromes, termed frontier airdromes. In crossing the frontier, they must follow a route determined by the administrative authority (Pr. Art. 14; Conv. Art. 15, par. 2).

Certain types of aircraft may, by reason of the nature of their work, be excused from landing on the frontier airdromes. The permit designates, in this case, the airdrome of arrival and departure, the route to be followed and the signals to be given on passing the frontier.

Chap. 3. Air Traffic Police

Art. 31. The commander, pilots, mechanics, and all other persons connected with the operation of an aircraft must have licenses under conditions determined by ministerial decree.

Licenses of commanders and pilots of French aircraft making international trips can only be granted to Frenchmen (Pr. Art. 8; Conv. Art. 12 and 13).

Art. 32. No aircraft can engage in air traffic unless it has been registered and is provided with a navigability certificate, issue after inspection of the machine, under conditions determined by ministerial decree.

The decree will further determine the pieces to be carried on the aircraft and the marks to be painted on it (Pr. Art. 6, 7 and 9; Conv. Art. 11, 19 and 20).

Art. 33. Without special authorization, aircraft are forbidden to carry explosives, arms and war munitions, homing pigeons and objects of correspondence comprised in the postal monopoly.

Transportation and use of photograph cameras may be forbidden by ministerial decree (Pr. Art. 11; Conv. Art. 26 to 29).

Art. 34. No radio instrument can be installed on an aircraft without special permission.

Aircraft assigned to a public passenger transportation company must be provided with radio instruments under conditions to be fixed by decree.

In every instance, men assigned to radio service must be provided with special licenses (Pr. Art. 12; Conv. 14).

Art. 35. Every aircraft, landing on an airdrome, is subject to inspection and surveillance by the administrative authorities (Pr. Art. 13; Conv. Art. 21).

Art. 36. Every aircraft in circulation, wherever it may be, must submit to the orders of the post office department and to the police and customs aircraft, under whatever form such orders may be given (Pr. Art. 13; Conv. Art. 15, par. 1).

Art. 37. Aircraft flying exclusively over airdromes and regions assigned by administrative authorities as experiment fields are not subject to the conditions required by law for air traffic.

They cannot, however, carry passengers, unless provided with navigability certificates (Pr. Art. 21).

Art. 38. Certificates of navigability and licenses, issued by the government whose nationality the aircraft possesses, are honored for flight above French territory, if the equivalent has been allowed by international convention or by decree.

PART III.

Air Traffic

Chap. 1. Transportation of Merchandise

Art. 39. A contract for carrying freight is confirmed by a way-bill or receipt. This document must contain, in addition to the stipulations of Art. 102 of the "Code de Commerce," the statement that the shipment is to go by air.

Art. 40. The carrier must fill out a manifest, designating the nature of the merchandise carried. A duplicate of the manifest must be carried on the aircraft and must be shown on demand to agents of the traffic police and to customs agents.

Art. 41. The carrier is responsible for loss or damage of goods carried, aside from acts of Providence or defects inherent in the goods.

If, however, the value of the goods is not declared by the shipper, the responsibility of the carrier is limited to 1000 francs for each package.

Art. 42. The carrier may, by special clause, free himself from the responsibility otherwise devolving on him by reason of the risks of the air and of errors committed by the crew.

This clause relieves the carrier of responsibility only on condition that the aircraft is in good navigable condition on starting. The administrative certificate carries a presumption of navigability, which may, however, be overthrown by proof to the contrary.

Art. 43. All clauses are null, whose object is to relieve the carrier of responsibility for himself or his subordinates, in loading, storing and delivering goods.

Art. 44. The commander has the right to have the merchandise thrown overboard during the trip if it is necessary for the safety of the aircraft. If a choice is possible, he must throw overboard merchandise of small value. No responsibility devolves on the carrier, toward the shipper and addressee, for this loss.

Art. 45. With the preceding exceptions, the rules of the "Code de Commerce" relating to transportation by land and water apply to transportation by air.

Chap. 2. Passengers

Art. 46. The contract for carrying a passenger must be confirmed by the issuance of a ticket.

A list is made of the names of the passengers, a duplicate of which must be kept on the aircraft and communicated on demand to agents of the traffic police.

This does not apply, however, to round non-stop flights back to the airdrome of departure.

Art. 47. For international transportation, the carrier can only accept passengers, after making sure that they are regularly authorized to land at the point of destination or intermediate stations.

Art. 48. The carrier may relieve himself of responsibility for accidents to the passengers in accordance with the provisions of Art. 42.

Chap. 3. Renting Aircraft

Art. 49. In case an aircraft is rented for several successive trips and for a given period of time, the commander, pilot and crew remain, except on agreement to the contrary, under the orders of the owner of the aircraft.

Art. 50. The owner of an aircraft let to a third party re-

Digitized by Google

mains subject to the legal requirements and is held responsible, together with the renter, for their violation.

However, if the renting contract is recorded in the register and if the renter fulfills the required conditions for French aircraft, he is alone held responsible for fulfilling the legal obligations.

PART IV.

Responsibility for Damages

Art. 51. Pilots are expected to conform to the regulations with reference to the air traffic police, to the route, to the lights and signals and to take all necessary precautions for avoiding accidents.

Art. 52. In case of damage done by an aircraft in flight to another aircraft in flight, the responsibility of the pilots and of the owner of the aircraft is regulated in conformity with the provisions of the civil code (Pr. Art. 5, par. 2).

Art. 53. The owner of an aircraft is responsible for damages caused by the evolutions of an aircraft, or by objects becoming detached from it, to persons or property on the ground.

This responsibility can be escaped only by proving the fault of the victim (Pr. Art. 5).

Art. 54. It is forbidden to throw from an aircraft in flight except for urgent reasons, any objects whatsoever, with the exception of the regular ballast (Pr. Art. 15, par. 2).

In case objects or the regular ballast, thrown out by necessity, cause injury to persons and property on the ground, the responsibility will be regulated in accordance with the provisions of the foregoing article (Suisse, Art. 22).

Art. 55. In the case of a rented aircraft, the owner and the renter are jointly responsible toward third parties for damages inflicted (Suisse, Art. 26).

However, if the renting is recorded in the register, the owner is responsible, if the third party proves fault on his part.

Art. 56. The suit for damages may be brought, at the option of the plaintiff, either before the court of the town where the damage is done, or before the court of the town where the defendant resides.

If it is an injury done an aircraft in flight, the court of the place of injury is the one within the jurisdiction of which the victim is obliged to land after the injury (Suisse, Art. 32).

Art. 57. The law of April 29, 1916, on martime assistance and salvage applies to aircraft in peril at sea and to the pilots of aircraft who can lend assistance to persons in peril (Pr. Art. 17 and 18; Conv. Art. 22 and 23).

Art. 58. Any one who finds the wreck of an aircraft must report it to the municipal authorities within 48 hours of its discovery. Any infraction of this requirement is subject to the penalties in Art. 475, par. 12, of the penal code (Pr. Art. 18).

The rules regarding maritime wrecks apply only to aircraft found on the sea or seacoast (Conv. Art. 23).

Art. 59. In case of the disapearance of an aircraft without news, it is considered lost three months after the date of the dispatch of the last news.

The death of the persons on an aircraft may, after the expiration of this period, be declared by the application of the law of January 8, 1893.

PART V.

Penalties

(Under this head, there will be inserted the penal provisions in the legislative bill drawn up by the government.)

(Translated by the National Advisory Committee for Aeronautics.)

AIR SERVICE IN COMBAT IN CONJUNCTION WITH OTHER ARMS

By MAJOR H. H. ARNOLD,

Corps Area Air Officer

(Speech Delivered at meeting of the Association of the Army of the United States, May 22, 1922).

IN delivering this talk today two thoughts primarily impress themselves on my mind. The first is that I was told by one of the officers of this organization that in order to make an acceptable address I had not only to talk as if I were convinced that the Air Service was the most important branch of the Army, but also to convince everyone else of the same thing; and, second, that there was probably no other branch of the Army so freely "cussed out" during the World War as was the Air Service. In order that you may obtain the background for the picture of Air Service in combat it is essential that I digress for a few minutes from that subject and outline in a very general way the fundamental preliminaries which must be gone through to properly prepare for an efficient all-around combatant Air Service.

The structure around which any Air Service Unit is built is the Pilot. The success or failure of any mission, either in peace or war, in the Air Service depends upon the resourcefulness, stick-to-it-iveness, fearlessness and self-confidence of the pilot. In selecting personnel suitable for pilot training there are certain fundamental qualities which if it is known that an individual possesses make him immediately eligible for training without question. These qualifications may be outlined as: initiative combined with daring; willingness to sacrifice for military good; confidence, capacity for sustained suspense; interest, and perfect health. During the World War the average life of a pilot on the front was about three months. At the end of that time he had either been shot down, injured in a crash behind our own lines, or had developed nerves to such an extent that he imagined moderate difficulties and obstacles so as to make him unfit for further service. It is true that certain pilots last much longer than three months, but they were the exception rather than the rule.

The training of all Air Service personnel was conducted with a view of taking complete advantage of the qualities already outlined and utilizing to the fullest extent the short life of these men while they were on the front. Candidates for the Air Service were selected after having been given a thorough physical examination including a re-breather test. This test made it possible to determine at the start whether or not the candidates could control their entire physical and mental faculties at altitudes above 15,000 feet. Having been given this preliminary examination they were sent to a primary flying school where they were taught the fundamentals of flying, and—from actual observation segregated into groups according to their personal qualifications. These groups were: The very best pilots—*Pursuit;* extremely reckless but good gunnery—*Ground Attack;* calm, mathematical and exceptional concentration—*Artillery Observation;* exceptional knowledge of maps, distances and map reading *Photography;* exceptional vision, good in map reading and above average in gunnery—*Deep Reconnaissance.* The preliminary training of all pilots included fundamentals of radio, photography, attack, bombardment and gunnery. After they had been classified for special work they were given comprehensive courses in the subjects most necessary for their particular branch of flying.

The primary duty of any Air Service in battle is to clear the skies of all enemy air service,—this includes all hostile Lighter- and Heavier-than-air craft. The other duties, such as reconnaissance of artillery fire, bombardment and ground attack are all of secondary importance, for it is readily seen that if the enemy air service is permitted to observe for their own artillery, bombard masses of troops, supply stations, ammunition dumps, etc., photograph at will behind our lines and harass our own Infantry by ground attack, any work of a similar nature done by our own Air Service would be completely counterbalanced and no practical benefit would be derived therefrom. The statement so often made by officers and enlisted men in the other branches during the World War was that while they saw many German aeroplanes they seldom, if ever, saw any Allied planes in their section of the line. Further, apparently our own troops did not recognize our own planes when they saw them, for our own Infantry in the front lines quite frequently fired on Allied planes. It was, therefore, necessery, in order to keep our troops from firing at Allied aeroplanes, to post signs in conspicuous places where all troops could see them with the insignia used by our own Air Service on these signs, together with a request: "Do not shoot at aeroplanes using this insignia for they are your friends and are trying to help you." At about the time our own troops were making statements of never seeing Allied planes, the German troops were stating just the opposite. Shortly after the Armistice a German Artillery Officer was interviewed in Metz and he asked the question as to where the Allies secured all their aeroplanes, because while he was up on

Digitized by Google

the front he saw many Allied aeroplanes but seldom, if ever, saw a German aeroplane.

In figuring out a plan of operation which will preclude the crossing of our own lines by enemy aeroplanes it has always to be borne in mind that Air travel is entirely different from ground travel in that aircraft can operate in three dimensions. There are no set roads to follow; they move so rapidly that they are seen only for a short time before they are actually present; they can change their course at will, making it impossible, as a general rule, to anticipate their destination. It is obviously impossible to have a constant patrol of combat aeroplanes along the entire front so dense that it will prohibit the crossing of hostile planes,—for while the patrols are operating from the ground to altitudes of 3000 feet, enemy planes could get over at five, ten or fifteen thousand. The enormous number of planes to be used in such a patrol to make it absolutely impenetrable would be entirely too great for the benefits which would be derived therefrom. However, in order that protection against hostile aircraft raids can be given, the generally accepted plan of operations is to have patrols over certain areas carried out at intervals,—the remainder of the combat Air Service to be held in readiness at the aerodromes. The presence of hostile aircraft is made known by calls from the ground troops; by anti-aircraft fire; by report from balloons or by actual observation of the pursuit planes on patrol. After their location is actually determined by one of the above methods a concentration of our own combat planes is made with a view of driving them down or back across the lines. These hostile planes might be crossing the lines for the purpose of carrying out any one of several missions, such as observing for artillery; taking photographs, bombarding ammunition dumps, supply stations or masses of troops, or harassing the Infantry. In any one of these cases, however, the method of defense is the same. After the hostile planes are located our own pursuit planes converge on that sector in such a manner as to insure that enemy's mission will not be executed.

One of the most disagreeable tasks in connection with protection against hostile aircraft is night pursuit work. This requires pursuit planes to leave their aerodrome in the dark with a view of locating hostile bombardment planes which might or might not have been located by searchlights and drive them down before they execute their missions. In order to properly perform this duty these pilots must have absolute confidence in their planes and must not know the meaning of the word "fear", for after once leaving their own aerodromes they are entirely dependent upon the reliability of their engines. Emergency landing fields cannot be seen at night and the pilot's only salvation is in his being able to return to a friendly aerodrome and by giving the Very pistol signal already agreed upon have the landing lights turned on the field prior to his actual descent.

In actual combat in the air there are certain well-defined rules which must be carried out in order to insure success in an engagement. Every aeroplane has what is known as a "blind spot". This is caused by parts of the aeroplane masking the pilot's or observer's vision. There are certain other sections in which an object can be seen but cannot be fired upon from the aeroplane due to interference by parts of the plane itself. An experienced aviator knows as soon as a hostile aircraft is seen where the blind spots are and the best method of attack. In order to eliminate these blind spots patrols ordinarily fly in a "V" formation. This enables the blind spots of one aeroplane to be covered by the guns from the other planes, and as long as the formation is kept intact any attacking force will be under fire at all times. The tactics of the air, therefore, contemplate maneuvers so that the formation will be broken,—usually by the least experienced pilots who get nervous or panic-stricken. As soon as the formation is broken it is an easy matter for the experienced pilots to approach the individual planes either by a straight dive from above or by a zoom under the tail and secure several machine gun bursts on the plane before being seen. The melee which ensues after a formation is broken was commonly called during the World War a "dog fight". Many an inexperienced pilot lost his life on account of his leaving the formation through fear, becoming rattled or due to mechanical trouble with his plane.

One of the first things a pilot learns in combat is that if he gets between the sun and his opponents he can attack almost at will. Another favorite method of attack is to have a decoy of one lone plane cruising around below a mass of clouds, and when hostile planes picked on it as something easy a whole formation comes out from in back of the bank of clouds and converges on the assailants.

The most important function of the Air Service in conjunction with the other arms is the securing and transmitting of information concerning the developments in and beyond the line of battle. This work has been in the past rendered most difficult because the limitations and possibilities of the Air Service were not sufficiently well known to the staff or to the troops, and the unreliability of the radio. The work of keeping the command informed is done by visual reconnaissance and reporting by radio, such as in artillery observation and by photographic missions. An aeroplane cannot stand still to observe and troops on the ground cannot be compelled, if they are hidden, to expose themselves; although in many instances a low-flying aeroplane by circling over a point suspected to conceal hostile troops has made them reveal themselves either due to their curiosity or their fear of bombardment or being shot at. A reconnaissance mission may sometimes fail, due to weather conditions such as fog or low clouds. In this connection an incident which occurred in the Argonne is to be noted. One of our crack pilots took up a brand new Observer. As he was about to cross the line he noticed that the "Archies" opened up with unusual intensity and that beyond the lines there was a low bank of clouds. After very skillful dodging he penetrated the barrage of "Archies" and flew low through the clouds to his objective. The pilot saw conditions which made him anxious to return with the news,—so that after a very hazardous flight he returned over the waiting General who was to receive the report, and the Observer dropped the message. After landing at the airdrome the pilot asked the Observer: "What message did you drop?" The Observer replied: "I dropped him this message: Would liked to have gone over the lines and completed the mission but there were too many Archies."

To the experienced aerial observer certain things show up on the ground more or less clearly due to the background and shadows. Soldiers standing on the line where two fields meet are hard to see, while if they are a few feet away from the line they become readily visible. Wheel tracks and paths are easily noted. Freshly turned earth is very conspicuous and no amount of camouflage can completely conceal it. To locate troops on broken ground requires flying at altitudes of seven hundred feet or less at which altitude aeroplanes are extremely vulnerable to machine gun fire from the ground. A mission which is often given to the Air Service is to locate the advance line of the Infantry. This mission is most difficult to perform as a general rule on account of the Infantry being too busy or their having no inclination to show their panels. Then, on the other hand, there is a certain fear that if they do show their panels they are locating their position to hostile aircraft. During the World War a certain Infantry Regiment on the front line was visited by an Air Service Officer, and when the command plane which was sent out to locate their front line had fired off the predetermined signals which established its identity, the infantry battalion did not display its panels. The Air Service Officer asked why the panels were not displayed and he was told that they would not display their panels for any aeroplanes because as soon as they did a Bosch plane would see the panels and in a few minutes all the hardware in Germany would be rained upon them. However, the aeroplane can, with the co-operation of the front line Infantry, establish for the Commanding General the exact location of the front line troops more accurately than can be done in any other way.

Aerial photographs, if taken under proper conditions, will show the minutest details of the ground. In order to properly interpret them, however, considerable experience must be had in that line of work, otherwise data of the utmost importance will be seen but not appreciated. When the air is clear and there is no haze, the taking of aerial photographs is simple, but with unfavorable weather conditions and artificial hindrance such as smoke considerable difficulty is experienced in securing the results desired. When the Commanding General of troops desires information concerning the area back of the enemy's lines he cannot wait for the clouds to clear or the smoke to blow away. To remedy these cond tions certain improvements have been made on cameras which make it possible now to take fairly clear and distinct pictures in spite of haze and smoke. Under ideal conditions it is now possible for an aeroplane to leave its airdrome, fly fifty miles, take a photograph or a series of photographs, return with them to the airdrome, develop the films and print the pictures and have them in the hands of the staff requiring them,—all within one hour and forty minutes.

Artillery observation is most satisfactorily performed by aeroplanes making figure eights over the objective and sending in to the artillery command station the results of the firing by radio. That would be the ideal way of carrying it out provided the enemy did not have the habit of trying to drive the planes home while they were at work. For the shorter ranges the best observation is performed by the captive balloons. These Balloons ascend to altitudes of about 3000 feet and practically are nothing more or less than an elevated platform 3000 feet above the ground. From this point, by the use of field glasses, they can spot every shot fired and its relation to the target. As the range increases it becomes necessary to send artillery observation planes over to report on the results of the firing regardless of hostile interference. In some instances, provided the results expected warrant it, it may be necessary to use Pursuit planes to protect the Observation planes while they are on that mission; but ordinarily the observation planes must be self-sup-

Digitized by Google

porting. While the Observer is locating the shells which fall the pilot must guide his ship so that the target is always under constant observation by the Observer and at the same time the pilot and observer both must keep on the lookout for the attack of hostile planes. A few other special missions which observation aeroplanes carry out are finding the enemy's lines; reporting location of and relaying signals from our own front line infantry; repeating instructions to our advance lines; indicating where resistance to advance will be met; using at critical moments the guns and bombs mounted on the aeroplanes against points of resistance and verifying reports received which are thought to be of value.

The principal Air Service offensive operations against ground targets are bombardment and ground attack. Points most usuallly designated for bombardment objectives are; ammunition dumps, railroad stations, cantonments or masses of troops, storage areas within the fighting area, and manufacturing plants, railroad stations and large supply stations beyond the fighting zone. Unless they are of such large size as warrant special attention these objectives within the fighting zone are usually bombarded by the day bombardment aeroplanes and those objectives beyond the fighting zone are usually bombarded by the night bombardment planes. The main difference between the day bombardment and the night bombardment planes is the radius of action and load carried; whereas, the day bombardment planes have a radius of action of about 300 miles, the night bomhardment planes have a radius of action of from six to eight hundred miles. The day bombardment planes can carry a load of three or four hundred pounds of bombs and the night bombardment planes can carry a load of bombs up to two thousand pounds. The day bombardment planes are able to go over the lines at an altitude of from eight to twelve thousand feet, while the night bombardment planes go over the lines as low as fifteen hundred feet.

Ordinarily the day bombardment planes rely on the "V" formation for their safety. In certain instances where enemy aircraft are known to be in extra heavy force Pursuit planes are sent along as a convoy until they have passed the front line of the enemy's airdromes. In order to make their report complete after return to their home airdrome in the majority of day bombardment raids one plane is equipped with a camera and takes pictures of the objective together with its appearance before and after the bombs have been dropped. During the War, usually either while the bombs were being dropped or after they had been dropped the bombing forces would be attacked by enemy planes and would be forced to fight its way home. The night bombardment planes rely principally upon darkness for their protection. They fly at low altitudes, make their attack and then usually return by another route so that they will not he intercepted as they cross the lines.

During the War the Air Service while engaged in infantry missions learned from experience that it could cause much consternation amongst hostile ground troops hy flying low and dropping small 15-lb. hombs among groups of men or light artillery, and in some cases by actual machine gunning troops in the trenches or assembled in a mass along roads or other places. The actual physical results of these ground attacks were probably not very great, but there is no question as to the effect on the morale of the troops. In several instances during the German retreat aeroplanes were so fortunate as to see portions of roads crowded with convoys and masses of troops and were able to fly down on them and drop a few bomhs and then turn and come back sweeping the road with machine gun fire before the surprised columns could take cover or scatter.

This class of work necessitated the design and construction of a special type of aeroplane called the "Ground Attack" plane. The sole purpose of this plane in combat is low flying over the lines engaging with its machine guns such hostile forces as present a favorable target. This machine has mounted in it a 37 mm. gun which can attack tanks with an assurance that if it makes a hit the tank will probably be put out of commission. In the design of this plane armor plate is incorporated to such an extent that the engine, radiator, gas tanks and personnel are completely covered and safe from small calibre guns. This pract.cally insures the safety of the plane and its personnel while ti is flying over the line.

In the St. Mihiel offensive the Air Service was called upon to perform more continous and harder flying than in any other offensive. The plan of operations as outlined for them neccessitated the utilization of not only the entire American Air Service available but attaching to it a certain number of French and British Air Service Units. Our first Army in that operation was composed of the 1st, 4th and 5th American Corps and the French 2nd Colonial Corps. Each Corps had assigned to it an Observation Group which was a component part of that corps and under the direct orders of the Corps Commander. Observation Group for duty with the Army was formed for taking care of all long-range day reconnaissance. Another Observation Group was used for regulating the Army Artillery. In addition to this there were quite a fw bombing squadrons and sveral pursuit groups. The total aeroplanes used in this operation were: 701 Pursuit planes; 366 Observation planes; 323 Day Bombardment Planes and 91 Night Bombardment planes, a total of 1481 planes which was the largest Air Service force that had ever been engaged in one operation any time during the progress of the war. In spite of the fact that during the first three days of the operation the weather was bad, command, observation, surveillance and infantry attack planes all accomplished their missions. However, on one day only was it possible to send out photographic missions. The Observation planes penetrated as far as sixty kilometers beyond the enemy's front line at a time when rain was falling heavily and clouds prevented flying at an altitude above 3000 feet.

There were also under the command of the Commanding General, 1st Army, fifteen American and six French Balloon Companies. There were approximately twelve enemy balloons opposite the American Sector. The American Balloon Companies moved forward with the advancing line and on the third day of the offensive were sufficiently well-posted to regulate artillery fire and send in additional important information to Corps and Divisional Staffs. During the four days of the offensive the twenty-one balloon companies had moved forward a total distance of Two Hundred Two Kilometers. Despite handicaps of weather, etc. the Air Service contributed materially to the success of the St. Mihiel operations. The Staff was kept informed practically hourly by clear and intelligent reports; hostile air forces wee beaten back whenever they were encountered; rear areas were watched, photographed and bombed.

Here is what the Air Service did in the last war. It located our own front line and hostile line for the Commanding Generals; took photographs of the terrain in back of the enemy's line for the General Staff; observed and reported on shots fired for the Artillery; bombed and raked with machine gun fire hostile machine gun nests, and points of resistance for the Infantry; carried important personages and supplies for the Quartermaster Corps; made strategic reconnaisances for the Cavalry and messages for the Signal Corps; in especially constructed ambulance planes carried wounded needing immediate attention for the Medical Corps—and in the great battle of Paris the young pilots put on the dog—for the whole Army.

AIR TRAFFIC

By G. SUDRE

HARDLY had aviation emerged from the experimental stage before France began to think of the improvement in international relations which should accrue from the conquest of the air. Nothing could better demonstrate this desire for general harmony than the attempt made in 1910 by the French government to conclude an international aerial convention.

This project, not meeting everywhere the same concurrence, was abandoned. It was renewed, this time with success, when the considerable development of aerial navigation during the war of 1914-18 necessitated, at the close of hostilities, the solution of a series of questions, which had yet hardly been touched.

As regards air traffic, it was necessary to establish general principles, according to which aircraft could circulate in their own country and pass from one country to another.

National Legislation

This was the task undertaken by the convention for regulating air navigation, which was signed October 13, 1919, by the representatives of 27 governments. The exchange of ratification of this convention was delayed by the fact that the United States and Canada formulated certain reservations which had to be examined.

On the other hand, a certain number of neutral countries requested, before giving their adhesion to this convention, that another protocol be added permitting, under certain conditions, derogations of article 5 of the convention of October 13, 1919, an article which obliged the contracting countries to forbid the circulation, above their territory, of the aircraft of non-contracting governments.

While awaiting the ratification of the convention, provisional

Digitized by Google

agreements were made, on the basis of the principles contained in it, between France and England, France and Switzerland, and are now being arranged between France, Holland and Spain. A *modus vivendi* has been established on the same principles between France and Belgium.

The work accomplished by the convention of October 13, 1919, was considerable, since it established the general principles and the scope of international aerial legislation and has consequently determined the interior legislation, which must harmonize with the clauses of this general "chart of the air."

The importance of this document necessitates a brief summary. After establishing a few principles of a general nature, the convention enunciates, in chapters I, II and III, the rules to follow regarding the nationality of aircraft, certificates of navigability and certificates of fitness of pilots. Chapter IV is devoted to air navigation over a foreign country, and chapter V to the rules to be observed in starting, en route and in landing. Chapted VI treats of forbidden shipments (explosives, arms, ammunition, etc.) and chapter VII of government aircraft. Lastly, chapter VIII institutes a permanent body, the "International Commission of Aerial Navigation," which is "placed under the authority of the Society of Nations." This introduces a principle of a more general order than that of most international agreements, which are simple compromises between various and often conflicting national interests. The convention of October, 1919, was thus an attempt to realize an aerial society of nations.

The convention of 1919 having established international bases for national legislation, the French Government was enabled to resume its project of May 7, 1913, which had been abandoned after the failure of the proposed international convention of 1910.

A new legislative bill, signed by the ministers of Foreign Affairs, Public Works, Interior, War, Navy and Finance was deposited March 25, 1920, on the desk of the Chamber of Deputies.

The principles laid down in the convention of 1919 were faithfully followed and the consequences deduced. The rules adopted before the war by the decree of December 16, 1913, and which inspired the legislative bill of the same year, were adapted to the new circumstances and conditions of aviation. This bill, after various amendments, was adopted by the Chamber of Deputies and is now before the Senate.

On the other hand, while awaiting the action of Parliament, there was urgent need of harmonizing the French interior regulations, contained in a decree of December 16, 1913, with the new exigencies of aerial locomotion, as well as with the international agreements already made.

French Interior Regulations

The decree of July 8, 1920, responded to this need and laid down the general principles of aerial navigation in France. It left the details of regulation to a series of orders which appeared during the past year. These documents now constitute the French code of the air. A brief enumeration of the principal ones will sufficiently indicate the breadth and complexity of the problems studied, as well as the very advanced degree of organization already attained by air traffic in France.

Decree of August 9, 1920, regulating the employment of radio for protecting the flight of aircraft (Journal Officiel, September 2, 1920; *Bulletin de la Navigation Aerienne*, No. 7, October, 1920).

Decree of August 14, 1920, establishing the conditions for the issuance of certificates of navigability for aircraft (*Journal Officiel*, August 14, 1920; Bulletin No. 6, September, 1920).

Decree of August 14, 1920, fixing the registration rules for aircraft and the distinctive marks to be borne by them (*Journal Officiel*, August 14, 1920; Bulletin No. 6, September, 1920).

Decree of August 26, 1920, regulating air travel, beacons and signals (*Journal Officiel*, August 29, 1920; Bulletin No. 6, September, 1920).

Decree of September 18, 1920, relating to licenses for civilian pilots (*Journal Officiel*, September 24, 1920; Bulletin No. 7, October, 1920).

Decree of September 30, 1920, establishing the rules to follow in keeping books on aircraft (*Journal Officiel*, October 5, 1920; Bulletin No. 8, November, 1920).

Decree of January 12, 1921, establishing the customs regulations to be observed by aircraft landing in or leaving France (*Journal Officiel*, January 18, 1921; Bulletin No. 11, February, 1921).

Decree of June 10, 1921, regulating the transportation and use of photograph and kinetagraph cameras on aircraft (*Journal Officiel*, June 23, 1921).

Decree of June 10, 1921, abrogating previous dispositions relating to zones forbidden to aerial navigation (*Journal Officiel*, June 23, 1921).

Decree of August 23, 1921, doing away with the medical examination for the license of the pilot of a touring aeroplane (*Journal Officiel*, August 25, 1921).

Inspection of Aircraft and Pilots

Lastly, a certain number of departmental documents have determined the application of these decrees, as regards the supervision to be exercised over the pilot and aircraft, as well from the professional and technical point of view, as from the physical and material.

Thus the instructions of August 31, 1920, fixed the technical conditions to be fulfilled by aircraft for the obtention of navigability certificates. The instructions of September 18 and 28, 1920, fixed the professional and medical conditions to be fulfilled for the issuance, use and renewal of the licenses of civilian air pilots.

The above-mentioned decrees appeared in the *Journal Officiel* of the French Republic. All the supplemental instructions were published in the *Bulletin Officiel de la Navigation Aerienne.* These documents together give to aerial navigation the administrative regulations, in accordance with which it is expected to develop normally.

It was evidently necessary to regulate and coordinate carefully all improvements in aviation,, in their various manifestations, in order to avoid, in this branch of the industry which represents both mobility and speed any scattering of energy and anarchic incoherence and the consequent sterility of efforts and arrest of progress.

It must not, however, be forgotten that any regulation is beneficial only in so far as it is limited to the efficacious and discreet role of the internal framework, the invisible and robust skeleton of a living organism. It is a common characteristic of all fond and anxious mothers to fear all outside contact for their young children, and the French government, which, it must be confessed, is bending over the new-born Aviation with a passionate solicitude, has not been able to escape it entirely. It is thus that, as regards the customs regulations, the obligations of the technical supervision of the material and the conditions of the medical or professional examinations, certain requirements could be ameliorated without any real disadvantage. May the professional "regulator" be permitted to utter a vow not to regulate matters of the air with excessive prudence. In such matters the regulations of today are liable to become a dead weight by tomorrow, and weight is the enemy of the aeroplane.

Statistics

The development of air traffic is followed and confirmed by a monthly statement of the traffic of the French air lines in operation and a monthly report of accidents for each aerial navigation company. These statistics cover, for each line, the number of

(a) Trips scheduled, trips completed and trips partially completed;
(b) Kilometers flown;
(c) Paying passengers,
Non-paying passengers;
(d) Kg. of freight carried;
(e) Kg. of mail carried;
(f) Fatal accidents,
Accidents causing injuries,
Accidents causing only material damages.

From January 1 to September 15, 1921, the statistics for the French aerial navigation companies are:

1,617,119 km. flown;
8,068 passengers and 112,621 kg. freight and mail carried;
4 fatal accidents;
8 accidents causing injuries only.

Insurance

The matter of insurance in aerial navigation at present leaves much to be desired.

Since November 1, 1919, the French companies have combined in a "consortium" for carrying aerial transportation risks. The premiums in force are, unfortunately, high, the companies desiring to protect themselves amply, in new forms of insurance, against risks little known as yet. In fact, up to the present time statistics have pertained chiefly to war risks. The mean risk of commercial aviation can only be determined after about two years of general and carefully collected statistics. We have seen that such statistics have already been kept for several months.

Insurance rates will be greatly reduced when the "Bureau Veritas" completes the task it has undertaken of establishing an aeroplane register similar to that of the English Lloyd for ships.

(Translated by the National Advisory Committee for Aeronautics)

NAVAL and MILITARY AERONAUTICS

General Mitchell in Accident

Milwaukee.—Brigadier General William Mitchell suffered a fracture of three ribs as a result of being thrown from a horse May 28, when physicians made a diagnosis of his injuries. General Mitchell is at the home of his sister, Mrs. Arthur Young, here and will be confined to his bed for several days, it was said.

Training Operations Started at Ellington Field

Training operations, in which every qualified pilot of Ellington Field will participate, began on May 1st. The first week's schedule consisted of tactical formation training by squadrons of full strength. Pilots have been assigned in equal numbers to the 94th and 27th Squadrons.

Activities of the Trade Test Department at Chanute Field

Statistical reports show that during the period between December, 1919, and July, 1921, approximately 1450 students were placed in the Air Service Mechanics School, Chanute Field, for courses of instruction. Of this number 2.2 per cent were dropped for inaptitude, having failed to make the grade of 70 per cent or above. Prior to December, 1919, 32 per cent of the men entered in school were dropped via the inaptitude route, thus showing that the Trade Test Department has been successful in reducing the failures of the school by nearly 30 per cent. Statistics further show that during the functioning period of the Trade Test, approximately 100 men were rejected as being incapable of assimilating any course of instruction taught at the school, thereby effecting a great saving of money, in addition to upholding the morale of the various classes to a marked degree, inasmuch as a man of mediocre intelligence or a slow thinker would impede the necessary rapid progress which students must make.

The immense amount of time and energy expended in the placing of these men in courses which will prove most heneficial to the Air Service and to themselves is not shown in these figures. A conservative estimate of the number of interviews granted, by which the Trade Test Department has attained its enviable record, would reach close onto the five thousand mark, since it is found necessary in fifty per cent of the cases to change the men from their natural desires to a course best fitting their qualifications. The "Natural Desire" is usually the course for Airplane Mechanics or Airplane Engine Mechanics. In placing a man in a course of instruction, three important considerations must be dealt with, paramount among which being the existing orders from the Chief of Air Service that 22 courses of instruction be maintained and in constant operation; secondly, the man's qualifications; and thirdly, the man's desires. The orders from the Chief of Air Service require that a certain proportion of the students of this school be placed in each of the 22 courses which are taught, in order that each course may be operating at its full capacity at all times. This is necessary in order to supply the organizations with specialists in the wide and varied trades necessary to properly carry on Air Service work. To meet this condition, men sent to this school for instruction must in many cases be placed in courses which at the outset they do not desire. It can readily be seen that if these men were simply ordered to take a course and placed in that course without further notice, a great loss of efficiency would result, for while a man can be placed in a course of instruction he cannot be forced to learn nor to take an interest in his work. Men would be dissatisfied and the morale of the school would greatly suffer therefrom. The task of "selling" the various courses to the men devolves upon the Trade Test Department. It is something which requires tact, judgment, and a high degree of diplomacy, not to mention the great amount of time.

It is due to the great amount of attention and conscientious application given to this matter that the present efficiency of the Trade Test Department is, as before stated, 97.8 per cent. As a testimonial to the success of this method, several men who have completed courses have come to the Trade Test Department upon graduation and candidly admitted that in "selling" them the course of instruction, other than that which they thought they desired, the Trade Test had benefited them, and students, materially.

The compilation of statistical reports above mentioned does not cover the period from July, 1921, to the present date, and of this period much can be said. The first outstanding event in the life of the Trade Test Department for the period named was the ordering of the Chief Trade Expert to Mitchel Field, Long Island, N. Y., where he interviewed and trade-tested 600 enlisted men for the purpose of ascertaining their mechanical and mental qualifications. These qualifications were forwarded to the Chief of Air Service for file and reference. Closely following this, 150 men reported to the Air Service Mechanics School from Mitchel Field for courses, as a direct result of the trade-testing carried on shortly before. It is needless to say that these men proved to be very exceptional material, compared with a later detachment of enlisted men who had not been classified. Thus, the value of the Trade Test was again exemplified. Following this was a period of inactivity, due to the reduction of the army. However, with the transfer of the Air Service Mechanics School from Kelly Field, San Antonio, Texas, to Chanute Field, Rantoul, Ill., the old "go-get-em" spirit was again in evidence in the recruiting drive, which took place in December, 1921, and January, 1922. In selecting men for enlistment, all candidates were given a short preliminary test by the officer in charge of the recruiting station. If, in his estimation, the applicant was deemed desirable, he was sent to Chanute Field and given a trade test to further determine his qualifications. If found suitable for the Air Service by the board, they were enlisted. Before being placed in courses of instruction, all men enlisted were again trade-tested and their records made. During the recruiting drive 713 men were interviewed by the Trade Test Department to determine their qualifications for enlistment in the Air Service. Of this number, 119 were rejected by the Trade Test Department as possessing neither the mental nor mechanical qualifications for Air Service work. Of these 119 rejected men the Trade Test Department was successful in obtaining fifty for other branches of the Service. Again, the figures tell a story, but not the half of it. They do not tell of the midnight oil burnt, of the hoarse voices, of the meals missed, of the perspiration splattered and nobly shed through the line when the old thermo had contracted itself about the zero mark. The foregoing little tale of the Department speaks for itself. Now let us strike off at a tangent.

The Officer in Charge of this Department has so many titles that if he had a tin badge for each one and they were pinned on him, the admiring public would have serious difficulty in discovering his noble physiognomy beneath the mass of medals. In addition to this, he is the lowest ranking member of the school's staff and, therefore, catches every job which is tossed nimbly down the line. Having no alternative, he has to do the work. Nevertheless, he has spent, does and will spend many sleepless nights praying Heaven to send a still lower ranking officer to Chanute Field so that he can engage in the daily diversion of "buck passing." Somewhat of an idea of this man's activity may be gleaned from an enumeration of a few of his titles, viz.: Officer in Charge of Trade Test, E. & R. Officer; Information Officer; Athletic Officer; Publicity Officer; Morale Officer; Member of G. C. M.; Secretary of Officer's Club; Engineer Officer, 15th Observation Squadron; Transportation Officer, 15th Observation Squadron, and Athletic Officer, 15th Observation Squadron. Again a story is told, hut not the half of it—not a quarter of it. In addition to handling the duties aforementioned with enviable efficiency, this Department is also the recipient of all jobs, ordinary, extraordinary and otherwise, i.e., selling peanuts, near beer, austioning off left-overs from the flying circus, organizing baseball, football, and track teams, building tennis courts and baseball diamonds, running picture shows, promoting boxing matches and coaching athletic teams.

These are only some of the glorious tasks accomplished by this Department. It has done everything that is possible to be done on a large and well ordered flying field, even unto caring for the Pathe News camera man, who at one time infested the field for the purpose of photographing parachute jumps and other aerial activities. This Department is proud of its record. "Grin and bear it" is the motto; "Lay on MacDuff" is the slogan.

FOREIGN NEWS

Wireless Position-Finding for Aircraft

The British Air Ministry issued recently the following memorandum: Since October of last year a wireless "position-finding" system has been under trial to enable air pilots to ascertain their position when flying on the Cross-Channel Airways. This system has, on several occasions, proved to be of particular advantage in adverse weather conditions, and has been introduced as a regular feature of the civil aviation wireless service. It is a further development of wireless direction finding which, during the past two years has proved of such great value to air navigation.

Until last October direction finding work was carried out only by the Civil Aviation Wireless Station at the London Air Fort of Croydon, and was limited to giving a pilot his compass bearing from that station. The Direction Finding station at Pulham Airship Base, Norfolk, has been successfully operated as the second station of the system during the past six months, thus enabling two bearings to be taken simultaneously upon a single aircraft, and its position determined by plotting the bearings upon a chart, the point of intersection giving the aircraft's position.

Direct intercommunication between Croydon and Pulham is effected by radio-telephony, and the pilot can be informed of his position with a high degree of accuracy under normal conditions. The radius of action for giving position is approximately 200 miles from the control station, which in this case is Croydon. Although primarily designed for radio-telephony, the system is equally adaptable for radio-telegraphy; the change over being carried into effect by a simple switch in a few seconds. The position can normally be given within two minutes. Similar facilities can be afforded from Croydon to aircraft engaged on inland flights and services.

Several instances have already occurred in cases of fog and storm where pilots have been informed of their position and enabled to reach their aerodromes in safety. The most noteworthy occasion was in February last, when an aeroplane flying over the airway between Paris and London was navigated entirely by wireless, the pilot seeing the ground only on one occasion for a few minutes.

Pilots and navigators have been strongly urged in a Notice to Airmen which has just been issued explaining the working of the system, to make a practice of utilizing on every flight this important aid to navigation, as the experience gained in the use of position finding in good weather when pilots should be able to check the accuracy of the positions will add to their confidence and proficiency in using the system when flying in bad weather.

It is therefore hoped that they will take full advantage of the opportunity thus offered of increasing the security of air navigation.

British Seaplane Floating Dock

It is announced that the seaplane floating dock, which has been under construction at Sheerness Dockyard to the orders of the Air Ministry, has now been delivered as ready for service. For the present, the craft has been berthed in the Medway, near Port Victoria. The dock, which has an over-all length of 143 ft. and a lifting capacity of 200 tons, will accommodate two large modern seaplanes, has thirteen buoyancy compartments, each flooded direct from the sea and emptied by blowing with compressed air. The power for the air compressors is supplied by two oil-driven dynamos, which also provide the current for lighting and power for workshop machinery, capstans, winches and pumps. An interesting feature is the supply of petrol to seaplanes from a large storage tank on the deck by means of the Bywater hydraulic system.—*Flight.*

Franco-Roumanian Co.

The Franco-Roumanian Air Navigation Co., which has been running an air service from Paris to Prague and Warsaw, is now about to inaugurate an extension of their service from Prague to Vienna to Budapest. The new service is to run three times a week, and the time taken will be two hours from Prague to Vienna and about 1¾ hours from Vienna to Budapest.

French Seaplane Contest

The French seaplane contest (Marseilles-Monaco-Marseilles) was run off on April 19th, when six naval and two civilian pilots took part. M. Eynac, Under Secretary of State for Aeronautics, evinced the keenest interest in the event, and had flown, in a Goliath, from Paris to Marseilles, in 5½ hours flying time, a couple of days previously, in order to be present at the start and finish. The finish found M. Poiree, on a 135 h.p. Clerget-Caudron, the winner in 5 hours, 1 min., Brou on a Farman being second in 8 hours and 14 minutes.

Aircraft Industry in Austria

The Australian Aircraft & Engineering Co., has recently submitted a request to the Government for a subsidy to establish and develop the aircraft industry in Australia. The company states that, unless further orders are placed by the Government, it will be out of work in three months, on completing the six Avro aeroplanes it is now working on at Mascot, New South Wales. Australian timber is being used by the company, and it builds all parts of the aeroplanes except the engines.
Industrial Australian.

Aviation in Argentina

It is estimated that there are 173 aeroplanes in Argentina, of which 53 belong to the army. Of the total number, 88 are French, 30 are American, 24 are British, 4 are Italian, 11 are German, and 16 are of various makes. The Compania Rio Platense de Aviacion made 84 trips and carried 281 passengers between Buenos Aires and Montevideo up to March 1. The cost of the round trip between the two cities is 140 pesos, including the automobile transportation to and from the field. The time of flight is 1 hour and 45 minutes, in contrast to the trip of 9 hours by boat which costs 45 pesos. (Trade Commissioner George S. Brady, Buenos Aires)

Commercial Aviation in Peru

The existing transportation situation in South American countries appears to be one requiring considerable development, and to those who find it necessary to make frequent journeys over long distances it means much delay, discomfort and inconvenience. The remedy for this state of affairs would appear to lie in the advent of commercial aviation which, if organized along the proper lines, should tend to greatly facilitate travel and aid in no small measure in the development of those countries.

A recent issue of the *West Coast Leader*, Lima, Peru, prints an interview had with Gen. A. S. Cooper, Representative in Lima of the Peruvian Corporation, giving an interesting account of an aeroplane journey made by him to inspect his Company's properties in northern Peru, using one of the machines of the Cia. National Aeronautica. He returned safely from his trip after an absence of six days, having covered an area of territory which by normal means of transport would have required as many weeks.

In the course of his interview, General Cooper spoke as follows:

"My difficulty in making periodical inspections of our properties in Chimbote, Trujillo, Pacasmayo and Paita is the steamer communications. At the best, by using launches, motor cars and steamers, it is possible to do it in about 25 days. This means about 10 days' work, 15 days' waiting and traveling, with much discomfort and inconvenience. I managed to hit off a Paita connection, but gave up the problem in despair of steamer connection in anything like reasonable time for the other ports.

"It occurred to me to ask Mr. Mott to call, with the result that he assured me that his company could solve the problem without the slightest difficulty. He informed me that he made a specialty of safe commercial flying and offered to place an aeroplane and pilot at my disposal at what I considered a very reasonable price.

"A short consideration showed me that his propostiion would result in a very considerable economy, taking into calculation the saving of time and the various expenses incidental to a combined launch, steamer and automobile proposition as incurred in my last inspection. Although I had some small experience in England of flying during war time and was not so certain of the comfort and safety, I, however, accepted Mr. Mott's assurance and left at 11 a. m. on the 22nd, in an ordinary Standard Curtiss 90 h.p., with Mr. Moore as pilot. We arrived at Chimbote at 3:45, at landing in Supe for petrol. This was an amusing incident. Mr. Moore circled over Supe and cut off his engine three times and then proceeded to a landing ground about 1.5 kilometers from the town. He got out of the machine and lighted a cigarette, and I said: 'What happens now?' He replied, 'A burro will come with gasoline.' In a few minutes we saw the donkey coming over the Pampas, urged by his owner, with three tins of gasoline, equal to the number of times that Mr. Moore cut out his engine over the town. The humble, but necessary, burro supplied the flying power to the machine and we were soon off again. I finished my work at Chimbote in two days, and at 1:10 o'clock on the 24th we left for Trujillo, arriving at 2:25, and landing on the football ground.

"We left Trujillo on the 26th, at 1:35, after a very courteous 'despedida (farewell) by the Prefect, Colonel Dertcano, and landed at Pacasmayo at 2:30. Mr. Moore had never landed at Pacasmayo, but I had given instructions for a suitable spot to be marked out—the requirements were not fully understood, and we had to land on an incline and across wind. However, this did not beat the pilot, and with a wriggle and kick and a small pancake he brought the machine to earth in front of about 500 admiring natives, for whom the enterprising railway manager had run over a cheap excursion. Mr. Moore afterwards selected a suitable ground.

"We left Pacasmayo, homeward bound, at 6:30 a. m. on the 28th, and as flying is hungry work, I arranged for desayuno (light breakfast) at Chimbote, finished up some work there; left at 10:10, picked up gasoline again in Supe, and arrived at Bellavista at 2:45 in the afternoon, after a 360-mile flight from Pacasmayo. I ungrudgingly admitted after landing that Mr. Mott's assurances as to security, convenience and comfort had been entirely substantiated. At no time during the journey did I feel any sense of insecurity, and Mr. Moore was always ready to start at the time I decided. I was particularly impressed with the care with which he tried over the machine and engine each time before leaving the ground.

"Whilst passing over barren parts of the coast I took a nap on one occasion and read a book on others. Mr. Moore flies at a very even pace and at a height of between 2,500 and 4,000 feet, and hardly uses his controls when in the air—or did not appear to do so—and I felt that in case of any mishap he could have landed the machine in safety.

"At times we passed through patches of thin air and experienced some bumping which, to a comparative novice, is a little disagreeable, but the extraordinary control which Mr. Moore has over his machine minimized the discomfort, which probably would not be felt at all after more experience.

"Even on the barren stretches of coast the coloring is always wonderful, and when over the openings of the various fertile valleys the view is extraordinarily pretty, especially after leaving Salaverry and approaching Santa Catalina Valley. One sees Trujillo appearing in a beautiful green setting, with its neat squares and streets and eastern looking churches and coloring, and a little beyond the Inca remains of Chan Chan are very clearly marked, also with squares and streets.

"The Chicama Valley with its enormous extension of intensive sugar cultivation is also very notable, with the large factories of Cartavio and Casa Grande. At about 4,000 feet the whole valley is spread out before one.

"I was sorry when the journey was over and also to say good-bye to a most pleasant traveling companion, and I shall certainly repeat the experience when occasion offers. A trip of this kind opens one's eyes to the possibilities of carefully organized commercial flying, especially in a country of difficult communications like Peru."

Austria's Air Achievement

The Australian Controller of Civil Aviation, Colonel H. Brinsmead, has set about his task in a wholehearted manner as the aerial routes already started in Australia bear witness. In connection with this work Colonel Brinsmead has recently completed a 9,000 miles aerial tour on the "Bristol" Tourer provided for his use. The flight, during which thousands of miles of practically unknown country were traversed, ranks as one of the finest flying achievements which has yet been recorded. To carry out this trip by any other than the aerial route would have been practically impossible. This flight must be added to the aeronautical feats already achieved by such notable Australians as Sir Ross Smith and Lieut. MacIntosh, and speaks well both for the Australian flying spirit and for the British design and workmanship embodied in the machine.

Brancker Civil Aviation Director

The British Air Ministry announces:—

Major-General Sir W. S. Brancker, K. C. B., A. F. C., has been appointed Director of Civil Aviation in the Air Ministry.

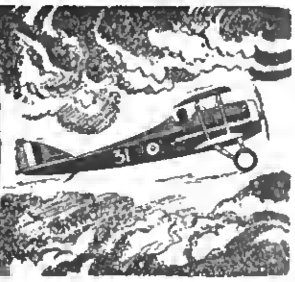
ELEMENTARY AERONAUTICS *and* MODEL NOTES



Model Aeroplane Details

(To be continued next week with illustrations of details mentioned)

DETAILS are an important consideration in anything, and especially in model aeroplanes. Therefore it would be well for anyone attempting to build a model to study carefully the drawings of the model, and more carefully study the details. Many of the I. M. A. C.'s so-called "secrets" are in this list of details; most of them have been used in the record breaking models and have enabled the club to capture and retain the whole ten of the officially recognized world's records. The records in no instance were made during freak weather conditions or from a favorable altitude—the field over which the land records were made being nearly as flat as the lake over which the Hydro records were made. These models hold their records on their merits alone, which means attention to details and design.

"CANS"—Tractor

Cans are one of the chief reasons for the light weight of the machines of the I. M. A. C. members. Even beginners, by the use of these cans, exceed the records held outside the club. The principle is so very simple—being the same practically as the eyelets on frail flexible fishing rods. By keeping the pull in either case more nearly parallel to the stick or rod, the fullest compressive strength of the material is utilized, because the sticks are not put to near so great a bending strain.

The first cans were really *cans* for they were in the form of a sleeve an inch or more in length and made from a tin can strip. Aluminum was then tried in the search for light weight. Then light strips of bamboo were used with a great deal of success for they were very light and stood a great deal of punishment; but one had to be very good at bending bamboo to make the small curves necessary.

Steel piano wire seems at this date to be the best for they are light, strong, and easy to form. The wire can even be flattened to streamline but this is not necessary. Great care should be taken not to get the cans too small or the rubber will catch on them. The size of the wire used is usually about as follows: No. 8 for six strands on a tractor, except the rear can which is always heavier to take the force of the rubber should it break, and others in proportion to the amount of rubber they must stand. The size of the opening runs about as follows: for two strands of 1/32" sq.—5/32" dia. cans; 2 st. ⅛" x 1/32 flat—7/32" dia.; 2 st. 3/16" x 1/32" flat—¼" dia.; 4 st. 3/16" x 1/32" flat—⅜" dia.; 5 st. 3/16" x 1/32" flat—7/16" dia.; and for 6 st. 3/16 x 1/32" flat rubber, ½" oval cans were used. The cans never receive any great strain except when the rubber breaks and this should not happen very often. However, care should be taken to fasten the cans securely to the stick for many contests have been lost through the loosening or losing of a can.

"CANS"—Twin Pusher

Twin push cans should be made of slightly heavier wire than is used for tractors on the same number of strands, because they are usually only supported on the one side. The opening may also be made larger for they do not take any strain unless the wing or a bad landing temporarily bends the motor-base, while the cans on a light tractor motor-base take some of the constant bending pull which must be kept as low as possible by small cans keeping the rubber close to the motor-base. In a twin there is no bending strain except at the rear can next to the propellers which can be stopped by a thread across the X brace. Two, or better still three cans is the common number for twin or tractor.

"S" Hooks

A—is the old style of "s" hook. It always slipped out of the winder or the front hook of the model and caused much trouble. B—is a much better shape of "s" hook for it will not tear the rubber when it is being slipped into the hook and if properly made it will not slip out of the front or rear hook as the case may be. There is more wire in it but it is a much better hook and is not much more difficult to make. C—is no better than B except that it can be made of lighter wire because of the safety hook arrangement. It is unhooked like a safety pin and the rubber inserted then it is locked up again. No. 5 wire will hold 2 strands of ⅛" flat rubber; No. 7, 2 st. 3/16" flat rubber; No. 11, 4 st. 3/16" flat rubber; No. 12, 5 st. 3/16" flat; No. 13, 6 & 7 st. etc. This covers all the power units common to I. M. A. C. models. One or two sizes smaller wire can be used with the safety hooks but that is getting on dangerous ground. Always have the one side of the "s" hook big enough to fit in the winder yet small enough to prevent it from coming unhooked during flight.

Twin-Push Motor Hooks

Hooks for large or small machines can be made as shown. A good plan is to have the eyelets that the "s" hook fits into longer than seems necessary in order that there will be no opening for the "s" hook to slip out of. The wire sizes are the same or one size larger than the "s" hook for the same number of strands.

Tractor Motor Hooks

Follow the same good plan of extending the wire past the upright piece on the part where the "s" hook fastens, to prevent the "s" hook from slipping around and coming out. When a frail wire hook is used the rear end of the eyelet should be twisted around the upright part of the eyelet to prevent it from coming out.

Hangers and Bearings

These hangers are of the lightest and strongest style as well as the simplest bearing in one piece yet devised. "C" shows a common nail without a head as used in making a bearing. "B" shows the nail flattened on both ends and drilled through the head end. "A" shows the finished hanger after being bent and the drilled hole countersunk from the rear, filed smooth, corners rounded, and the position it is mounted on a twin pusher.

Wire Bearings

Wire bearings suitable only on small models and then mostly on tractors. "A" shows one kind fastened to the top of the motor-base. "B" is a variation in which the one end is pushed through and bent on the bottom of the stick. This is not supposed to come loose but if "A" is fastened on well the extra trouble required to make "B" is wasted. Make the hole as round as possible.

Motor Base Sections

Motor base sections are an important consideration for at least one quarter or more often one third of the total weight is in the frame. "A" is the most common style of motorstick. It is generally pine or spruce planed to size with the corners well rounded for streamline. The size shown in the drawings would easily hold five strands and would hold six if well braced on a twin push. For a tractor it would just hold four strands and possibly five well braced with cans. "B" is a section of a hollow spar (incidently a section of B. Ponds record tractor). The easiest way to make these is to make a U-shaped section and then glue a cap on to it. The cap must be fastened securely. The spar should be held tightly against a flat surface while the glue is setting. The U-shaped section of the cap can be quickly made to the approximate size on a circular saw and finished with a plane and sandpaper.

"C" is the section of a Balsa spar suitable for six strands. This spar is well rounded to streamline it. "D" is practically a full size section of Mr. B. Pond's dual world's record channel-spar twin push frame. This frame stood five strands nicely. It was easily constructed with the use of a rounded wood-carver's chisel. "C"-"D" are not suitable for tractors but a Balsa spar of the size and shape of "B" should hold (hold in this case means just hold) five or six strands or about the same as a hollow pine spar of the size shown with walls .025" in thickness. "B" will hold 8 or 9 strands on a twin pusher.

Balancing Hook

A balancing hook for propellers is made from a small piece of piano wire. The shaft of fthe propeller "C" rests down on "B" and rests up against "A". With the aid of this hook the heavy side of a propeller can be detected and corrected. All propellers must be accurately balanced for the best results.

(*To be continued*)

RADIO DIGEST

Overland Radio of Air Mail Completed

Some time in the near future, when you are juggling with your controls and get on a moderately long wave, if you should happen to hear some one saying "This is Jones, on No. 6 night mail, westbound, in thick fog, altitude 3,000 feet," do not be surprised nor alarmed. You will be listening to one of the United States air mail planes reporting by radiophone.

The Air Mail Service is doing some wonderful pioneer work, despite the fact that Congress has been extremely niggardly in allotting appropriations to that important service. It is laying the foundation for the future commercial air transport that will revolutionize physical communication in this country. In addition to this, however, it is also developing the most modern form of instantaneous communication which will materially aid in removing the last remaining preventable cause of aircraft danger.

The splendid program of communication development planned by the Air Mail Service is now being completed and should be in full operation within the next six months. This program will include a complete network of intercommunication across the entire transcontinental air route, as well as complete means of intercommunication between aircraft and between aircraft and ground stations.

Radio Compass System Complete

In addition to this there will be a complete system of radio compass stations to guide machines straight to their destination, and there will also be radio field locaters, which will enable aeroplanes caught in a fog to spiral gracefully down to a safe landing in the center of the field, despite weather conditions. With these complete systems in full working condition night flying (which is imperative to a successful air mail service) will be made not only possible, but measurably safe.

The most remarkable thing about this development is the fact that the officers responsible for it did not permit the parsimony of Congress to interfere with their plans. Having been cut down to the last cent by an unsympathetic appropriating body, the officers simply changed their tactics and developed the more essential parts of the system first, and left the application of the entire system to a more favorable period. The story of their achievement is best told in chronological form, and it is a story of real historical value.

It began shortly after the inauguration of the Air Mail Service, when the only practicable route was between New York and Washington. In the latter part of 1919 extensive experiments were made with radio direction finders upon aircraft flying between those two cities. The instruments upon the aeroplanes were designed with the prime idea of simplicity compatible with successful operation, in order that a minimum amount of attention would be required of the pilot. These experiments were eminently successful, and as a result of them the surest method of air navigation has been developed—the radio compass.

During the period of these experiments it was realized that while the radio direction finder and the radio beacon stations would permit an aeroplane to determine its exact position, the system itself would not permit a pilot to make a safe landing in foggy weather when he had reached his landing field.

Radio Field Locater Developed

The solution to this difficulty, it was realized, lay in devising a system of radio communication that would indicate to the pilot just when he was over the center of his landing field, so that he could spiral gently down through the fog. As a result of this determination the radio field locater was developed successfully.

In the fall of 1920 radio communication and radio aids were applied to the big twin engined Martin mail planes and a radio operator was placed aboard the machines of this type. In the terse words of the official report upon these operations "great success was obtained and these radio adjuncts were developed to a practical point."

It was at this juncture, however, that Congress stepped in and put the brakes upon further rapid development by cutting down the already meager appropriations for this service. As a result of this situation the officials of the air mail service were compelled to abandon completely all further experimentation with radio apparatus aboard the aircraft, and due to the act of Congress the air mail planes have been flying for two years without any of these necessary means of communication.

In the mean time, however, the officers of the air mail were not to be discouraged by this situation; so, thwarted in their major purpose, they went ahead as best they could with the facilities at their disposal. The result is that after two years of intensive work there exists at the present moment a complete network of intercommunication across the country operated by the air mail service.

Fifteen Stations in Service

This communication service consists of no less than fifteen five-kilowatt arc wireless telegraph stations and one large radiophone communication. The former have a normal daylight communication range of approximately 400 miles, and of course, much further at night. In addition to their value as a means of intercommunication the stations can also be used for airplane control work—such as radio direction finding and for the purpose of issuing orders to pilots of mail planes while they are en route between two air mail stations.

Now that this ground system has been established, officials of the Postoffice Department, in a letter, inform me that the work of equipping airplanes with direct finders and radio telephones is now under way. The preliminary installation is now being made, and there is every prospect of the operation of a complete system on the planes within the next six months. The work is being done in conjunction with the plans for the development of night flying along the transcontinental air routes.

As a result of the splendid development program of the air mail service, the investment represented in the establishment of the transcontinental communication system has been wisely made, and from present indications the government will soon recover its cost in the amount saved from the transmission of messages. In this connection the report sent to me reads as follows:

"Our ground control stations now handle an average of about 600,000 words a month at a cost of approximately $0.007 a word, based on expenses of operation and maintenance over the whole circuit."

This in itself is a remarkable record, but when the possibilities of the system in connection with rendering safety service to aircraft are taken into consideration also, the value of the investment to the people of the country becomes apparent. There should be no stifling of the air mail development.—Jack Binns, in N. Y. Tribune.

Almost Twenty Thousand Radio Senders in U. S.

A survey of all radio transmitting stations licensed by the Department of Commerce shows that there are 19,067 stations. Of this number 15,495 are amateur stations, 348 experimental, 2,783 American ships, and the balance, 439, commercial stations.

Of this last number, there are today 274 broadcasting stations, known as limited commercial stations. They comprise universities, municipalities, newspapers, electrical manufacturers and retail stores, sending entertainment or information on weather, crops and market reports.

The growth of this class of radio stations has been remarkable; it jumped from sixty-seven stations a little over two months ago to 274 today. Applications are filed on an average of about three or four a day.

Transmitting Stations

Trans-oceanic	11
General public or "ship in shore"	31
Point to point	124
Broadcasting	274
American ships	2,783
Experimental	225
Technical and training schools	123
Amateur	15,294
Special amateur	201
Total	19,067

Amateurs by Districts

1—Boston	2,490
2—New York	2,313
3—Baltimore	1,831
4—Baltimore (Savannah)	319
5—New Orleans	699
6—San Francisco	1,616
7—Seattle	726
8—Detroit	2,393
9—Chicago	2,907
Total	15,294

The Department of Commerce does not regulate or record receiving stations and will not guess at the total number, now unofficially estimated at about a million and a half.

Pick With Care The Parts for Loud Speaker

By B. Bradbury

Radio Engineer, General Electric

After some weeks or months of listening to radio broadcast programs by the use

Digitized by Google

of head receivers, it generally becomes desirable to install a loud speaking device which will make the signals audible throughout the room and enable several people to hear from at the same time. There is also the further desirability of securing signal intensifiers loud enough for dancing or concerts, where the music must be heard throughout a fairly good-sized hall.

To secure this amplification and at the same time maintain the original quality of the signal, it is necessary to observe a number of precautions in the selection and operation of the apparatus used.

Assuming that the signal directly from the detector is of good quality and loud enough to be heard distinctly in the head receivers, our problem is chiefly concerned in the maintenance of this quality, since it is a comparatively simple matter to obtain the necessary intensity.

In order to eliminate or minimize loud speaker distortion it is necessary to know the causes involved. The source of trouble may be in the amplifier, in the loud speaker itself, or in both.

For good amplification of telephone signals the interstage transformer should be capable of giving a uniform transfer of voltage from about two hundred to three thousand cycles a second. A good many transformers in use do not do this, and their operation is one of the principle causes for unsatisfactory signals. For any particular plate voltage applied to an amplifier tube there is a corresponding value of negative grid voltage which should be applied in order to operate upon a straight portion of the characteristic curve, and thus secure uniform amplification. With forty volts on the plate the negative grid bias should be about one volt, and with 100 volts on the plate the grid bias should be about four volts negative. Standard amplifier tubes will generally operate with two tubes in cascade without overloading them. Where more volume is desired for very strong signals it is preferable to use for the third stage a small-power tube with three or four hundred volts on the plate. The grid voltage in this case should be about twenty to twenty-five volts negative. This will hold the plate current down to normal value and operate upon a straight portion of the characteristic. It is also well to use reactance coupling between the second and third tubes, as this will cause very little distortion and will give good amplification.

For connecting to the loud speaker, especially when using a power tube for the last stage, it is preferable to use an intermediate transformer with the proper constants, instead of placing the loud speaker directly in the tube plate circuit. This keeps the plate current out of the loud speaker winding and prevents the polarizing effect that it would have upon the diaphragm.

A two-stage amplifier will generally give enough intensity to operate a loud speaker in an ordinary living room, while the loud speaker mechanism itself may be of the head telephone type with a suitable horn. Some receivers operate very well at moderate intensities, but when very strong signals are applied to them they vibrate so violently that the diaphragms hit the pole pieces and produce harsh sounds instead of good reproduction of the original signals. To handle the proper amount of energy, therefore, the construction must be such that reasonably strong vibrations will not force the diaphragm to its limit of travel. The material and shape of the diaphragm are also important in determining the resultant tone qualities, since whatever natural periods of vibration it may have will bring out certain tones in greater proportion than they should be to the remaining tones of a musical selection.

The size, shape and material of the horn are likewise important factors in the final result. The high natural period of a small horn will tend to accentuate the higher tones to the exclusion of the lower ones. The material from which the horn is made should be some substance which will not vibrate readily and produce rattling sounds.—N. Y. Tribune.

Loop Aerial for Autos Made Upon a Parasol

Many types of portable wireless receiving sets have been devised, but in all cases it is necessary to provide a ground to complete the circuit and in most cases it is necessary to stretch an aerial when signals are desired. Neither is necessary in a new parasol receiver just recently perfected by John B. Taylor, consulting engineer of Schenectady.

This parasol outfit is very simple in construction and easy to operate. It is very compact and light. A loop aerial of braided copper wire, which is very flexible, is sewed to the covering of the parasol in parallel lines, resembling braid, near the edge. Either end of this wire leads through eyelets along the main road to the handle, where a small condenser and crystal detector are attached. By varying the condenser, the set may be tuned for the different sending stations' wave lengths. On this small apparatus on the handle are attached the headphones, and all that is necessary to hear the signals or concerts from any station within the range of a crystal receiver is to point the parasol in the direction of the station. It operates much the same as a loop aerial in this respect.

The parasol can be lowered just as easily as any parasol. There is nothing freakish about its apearance and when closed looks just the same as any other parasol.

Mr. Taylor has made frequent tests of the device in the vicinity of Schenectady and has been able to hear signals and music broadcast from WGY, when ten miles away. Evenings while motoring in his car, he raises the parasol in the back seat and can plainly hear the concerts from WGY while riding about the suburban sections of Schenectady.

Protest Radio Ban on Political Talks

Washington.—The American Radio Association is dissatisfied with the decision of the Government to refuse permission for the broadcasting of political speeches by Government radio and intends to seek a modification of the new rule.

F. W. Brown, executive officer of the association, said that he would take up the matter immediately with Secretary Hoover with a view to having him issue orders that beginning two weeks prior to the November elections and lasting until election day, candidates for public office shall be permitted to use the Government radio stations for broadcasting addresses during certain hours of the day.

"The majority of people are interested in politics," said Mr. Brown. "Through a canvass of the thousands of members in our organization, we find that approximately two-thirds are eager to hear the various men running for office. Such a step taken by the Government would meet with the approval of the majority of radio enthusiasts, we feel certain, providing that there is a limit of two weeks, and permissible during certain hours of the day only. We do not think that the air should be full of political speeches all day long, however."

The decision of the Government to refuse permission for the use of its radio service for broadcasting political speeches was announced on May 20, when Theodore Roosevelt, Acting Secretary of the Navy, notified representatives of the Woman's Party that he would be obliged to deny their application for the use of the naval radio service for broadcasting speeches and music on the occasion of the dedication of the Woman's Party headquarters in Washington on May 21. He gave as a reason that it had been decided to discontinue the practice of permitting naval radio to be used for political purposes.

The action of the Acting Secretary of the Navy caused surprise, as Secretary Denby was understood to have granted previously the permission sought by the Woman's Party received a letter from cation ceremonies the officers of the Woman's Party received a letter from President Harding withdrawing the acceptance he had given in December to the invitation to attend the dedication. No explanation for the declination was contained in the President's letter.

There has been considerable mystery over the action of the President and the Acting Secretary of the Navy. Nothing has appeared to indicate that either the President or Acting Secretary Roosevelt had any objection to the Woman's Party as an organization, but it is evident that the rule to refuse permits to use Government radio for sending out political speeches had a connection with the dedication of the party's headquarters.

Radio Controlled Aeroplanes

Control of aeroplanes by radio is recorded as a notable achievement in France. A large machine was taken up. The pilot allowed his "ship" to be maneuvered for over an hour by wireless operators in a land station far below. At a given signal the pilot resumed control and landed.

Government Gets Share Radio Boom

Over 2,000 per cent increase in revenue was derived by the United States Government from private and commercial radio stations in 1921 over the year 1917. The earnings of these stations are estimated to be in excess of $1,600,000 and show a profit of more than 15 per cent on the Government's investment of $25,000,000.

Sweden to Talk to America

Sweden expects to talk direct to America when the gigantic station in that country is completed. An agreement with the Radio Corporation of America and the Swedish State Telegraph Board will bring about the undertaking. Sweden's wireless communications are now dispatched from the station at Stavanger, Norway.

Aviation Material

Is usually wanted in a great rush, especially at this time of the year. YOU WIRE US WE'LL DO THE REST REMEMBER

Our stock is in our own warehouse READY FOR SHIPMENT A few of the items you may need in a hurry:

New propellers for OX5 motors for American Dee, Canuck and Standard. These propellers are coppertipped, of the toothpick and D-5000 type in Oak, Walnut, Birch and Mahogany, and are made to government specifications by Flottorp, Westmore, Liquid Carbonic Co., Packard, Buffalo Propeller Co., Fischer, Dayton Wright, Curtiss Co., and McCook Field. Diameters run from 8 foot to 8 ft. 4 in. Pitch from 5 to 8 ft. 8 in. Every propeller is guaranteed by us and boxed, ready for shipment. Price $25.00 each. We have a few untipped or slightly used at $20.00 each. Send for our list of OX5 propellers. New 150 Hispano propellers $28.00 each.

Water Proof Covers for all types of propellers, each	$ 2.00
New Air Speed indicators, complete with pitot head and copper tubing	10.00
New Oil Gauges, 100 and 120 lbs., 2-inch face, black finish	4.00
New Air Gauges, 10 lbs., 2-inch face, black finish	4.50
New Compasses, very small, Den. Elec. type, luminous figures and indicator	15.00
New Safety Belts, American Dee type	3.00
New DeH Leather Upholstered Wicker Bucket Seats	3.00
New Heavy Celluloid Sheets, 19 inches by 34 inches, per sheet	8.00
New Van Sicklen Tachometers, luminous dials	20.00
New Warner Tachometer Heads	5.00
New Warner Shafts, 7 or 8-foot lengths, complete	$ 2.00
New Wheels, complete with tire and tube, 700 x 100, with bushings to fit Curtiss or Standard	18.00
New Curtiss or Standard Radiators	20.00
New Black Shock Absorber Cord, per foot	.05
Pratt & Lambert Acetate Dope, 50 gallon barrels, at	40.00
New Side Cowls for Dee or Standard or Canuck, each side	12.50
New Stock Goodyear Cord Tires, 20 x 4	10.00
New Stock Goodyear Tubes, 26 x 4	2.00
New Wheels, 750 x 125, complete with new tires and bushings to fit Curtiss or Standard	25.00

Also every spare part for the OX5 motor and a large stock of parts for OXX6, Clerget, Hispano, Beardmore and Anzani motors. Full line of spares for American Dee, Canuck and Standard planes. Accessories and equipment for all aeronautical purposes.

Write for our catalog and price lists. Our information department is at your service.

Learn to Fly

Aviation is making such strides that it needs more men right now

You Can Learn To Fly

I can teach you how to become a successful pilot in a short time. My course is so arranged that you get only the things you need to make you a good aviator.

The Diggins Extension Course

is up-to-date, teaches you what you must know to become an expert flyer. This course is written by competent instructors right on my flying field. It is kept right up to the minute—all new developments in aviation are included. That is why it is recognized as the most complete and practical course offered today. My course saves you time and money because it prepares you at home so that you are ready to begin flying the day you arrive at the flying school.

Superior Points of the Diggins School

1. The Diggins school is the oldest, largest and most complete commercial aviation school in America.
2. The Diggins school is located in Chicago, the center of Aviation.
3. Living quarters and free employment service are maintained for students.
4. Diggins guarantees to make you a pilot.
5. Diggins' pilots get top notch salaries.
6. References, any aero club in America.

WRITE TODAY Write today for the new Diggins beautifully illustrated catalog.

RARE OPPORTUNITY

NEARLY NEW CANUCK, extra lerge wing surfece, large tail greup, nearly new rebuilt OXX moter, with new cepper tip Fiettorp; will cerry 3 enaily; linen perfect; rara bergain	$ 650.00
3 ether Canucks (one new flying) A-1	500.up
OX-5 meters, rebuilt end guerenteed	125.np
Complete eet of Standard Wings, new, curved, with wires, struts, centrel cable, tail group, creted	175.00
New Wings (cnvered) .....rights $50; lefts	70.00
New Winge (uncoversd) .....rights $35; lefts	55.00
OX-5—OXX-2—V2 pnrts at a sacrifice.	
Copper Tipped Tooth-Pick Flnttorp, new	24.00
Special OXX-6 Copper Tipped Flottorp, new	27.00
Mahogeny D-5000 plein tip, new	25.00

NEW MOTOR PARTS

Pistons (OX-5) $2.50; (OXX) $5.00	
Vaives $1.00 ench; OX-2 rocker arm $1.50	
Cylinders (OX-5) $15.00; OXX-6 $25.00	
Connecting-Rod, cnmplete with bearings	6.00
Canuck Blue-Prints	1.50
Instruments, eech	12.00

(All parts shipped iccoediately en receipt of 50% deposit)

DE LUXE AIR SERVICE, Asbury Park, N. J.

HARTSHORN STREAMLINE WIRES

Assembled with Hartshorn Universal Strap Ends make the Ideal Aeroplane Tie Rods—diminished wind resistance insuring greater speed.

This fact was proved in the speed test for the Pulitzer Trophy. Four of the first five ships were equipped with Hartshorn Streamline Tie Rods.

Write for circular A-1 describing our Wires and Strap End Fittings.

Gentlemen:

We feel it is only fair to let you know of the wonderful success we have had with Lakeside Aviation Oil.

After making dynamometer and short flight tests at Keyport we decided to make a real flight test on Lakeside Aviation Oil, so we used it on part of the record-breaking flight of the Aeromarine Cruiser "Santa Maria" between Chicago and Key West via the Mississippi River.

This Cruiser encountered most unfavorable flying conditions on the lower Mississippi, where Lakeside showed itself far superior to any of the many oils we had used. The consumption of Lakeside Aviation Oil over a fifty-hour period was less than half of the best oil we had then found.

Needless to say, we were very much pleased and have used Lakeside Aviation Oil in all our extensive operations, with the same wonderful results. We have proven the truth of your slogan "COSTS LESS PER FLYING HOUR".

Thanking you for insisting that we try out your oil, we remain

Very truly yours,

AEROMARINE AIRWAYS, Inc.

SPECIAL OPPORTUNITY

To Secure a Copy of the

Textbook of Aero Engines

By E. H. SHERBONDY and G. DOUGLAS WARDROP

Together With One Year's Subscription to

AERIAL AGE WEEKLY

The Leading Technical and Trade Aeronautic Publication in America

The Textbook of Aero Engines has been prepared for the purpose of having in one volume the complete information concerning all modern types of aero engines and an up-to-the minute discussion of the principles of aero engine design and construction, so that the reader may be able to undertake comparative research without recourse to a formidable list of volumes and publications, which in any event could only supply him with more or less obsolete information.

AERIAL AGE WEEKLY discusses and describes all current developments in the aero engine field, so that with the Textbook and consecutive copies of AERIAL AGE the subscriber will possess a complete encyclopedia on the subject.

To AERIAL AGE WEEKLY
5942 Grand Central Terminal, New York

Please send me a copy of the Textbook of Aero Engines (regular price $10.00), and enter my name on your subscription list for one year (regular price $4.00). I desire to take advantage of securing both at the special price of $10.00, and am enclosing my check for that amount herewith.

MF FLYING BOATS

We have purchased from the Navy all the remaining MF Flying Boats, 57 in number.

These are new, unflown and in perfect condition.

Our prices are:

MF Flying Boat, without engine, f.o.b. Philadelphia or f.o.b. Pensacola, Fla. **$675.00**

MF Flying Boat, two seater, with 100 H. P. OXX6 motor installed, ship completely tuned up and ready for flight, f.o.b. College Point, L. I., N. Y....................... **$1700.00**

MF Flying Boat, reconverted to 3 seater, equipped with 150 or 180 H. P. Hispano, f.o.b. College Point, L. I., N. Y. Model CK-14 .... **$2900.00**

This is a **real opportunity,** probably the last of its kind.

Utility!

People who know little about aeroplanes may think they are useless playthings—simply hobbies for men of wealth. Curtiss experience, however, disapproves any such idea, as most of our purchasers are people of moderate means—and most of our sales are made for useful commercial purposes. From the hundreds of valuable uses to which Curtiss aeroplanes are placed, a few are:

COMMUTING
TAXI SERVICE
AERIAL EXPRESS
CAMPAIGNING
SELECTING LAND SITES
OILFIELD SURVEY
CARRYING PAY-ROLLS
DELIVERING FRESH FISH
CIVIC PLANNING
FOOD DISTRIBUTION
FILM DELIVERY
AVIATION SCHOOLS
LAYING OUT LOGGING ROUTES
MAIL CARRYING
FOREST FIRE PATROL
AERIAL PHOTOGRAPHY
MAKNG MOTION PICTURES
RANCHING
MISSIONARY WORK

COMMERCIAL TRAVELING
DELIVERY OF CLEARING PAPERS
FIRE SURVEYS
CARRYING PRISONERS
VISITING REMOTE POINTS
RAILROAD SURVEY
PASSPORT DELIVERY
AERIAL TOURING
AERIAL ADVERTISING
ASTRONOMICAL OBSERVATION
EMERGENCY MEDICAL SERVICE
MARKETING GARDEN TRUCK
SHEEP AND CATTLE HERDING
SCOUTING FOR MARKET FISH
SURVEYS OF DOCKING
DELIVERY OF PERISHABLES
MACHINE PART DELIVERY
POLAR EXPLORATION
BASEBALL TRANSPORTATION

AMBULANCE WORK
WHEATFIELD SURVEY
AIR EXPLORATION
BOUNDARY PATROL
REAL ESTATE SURVEY
FUR CARRYING
CARRYING PRECIOUS ORE
HOSPITAL TRANSFER WORK
DELIVERING NEWSPAPERS
RY. TERMINAL SURVEYS
AERIAL FERRYING
LIFE GUARD
CARRYING REPORTERS
FORESTRY SURVEY
DELIVERING MAIL AT SEA
CARRYING PASSENGERS
AIR TRANSPORT

These useful enterprises offer numerous opportunities for owners of Curtiss aeroplanes. With good ready-to-fly used Jennies as low as $650.00 any ambitious pilot can get started. Many purchasers have paid for their aeroplanes in a single week from profits. Now is the time to buy!

From Portugal to Brazil by Air

THE Portuguese aviators who started from Lisbon for the South American coast have at last reached their destination, but instead of taking a few days the journey consumed more than two months, the first hop having been made on March 30. Captains Sacaduro and Coutinho did not play in luck; two of their machines were broken in landing and they had to wait at Fernando Noronha until new planes arrived from Lisbon.

Under the circumstances the voyage by seaplane from Portugal to Brazil, the first westward crossing of the Atlantic by a heavier than air flying machine, does not thrill the public as did the feats of the NC-4 and Alcock and Brown. The Portuguese made four stops between Lisbon and Permanbuco: the Canaries, the Cape Verde Islands, St. Pauls Rock and Fernando Noronha. This may sound like cautious proceeding, but some of the hops were of about 1,000 miles across lonely seas.

As the Portuguese Minister in Washington says, the voyage at least demonstrated the efficiency of the new methods of air navigation. The trip was slow but sure. To be able to reach such a tiny target as St. Pauls Rock required precision in instruments and their use. The aviators used a new type of sextant which is independent of the sea level horizon and another instrument which advised them of errors in their course more accurately than a compass could do.

So, aside from the sentimental triumph of the Portuguese in being the first Europeans to reach by air the great Western republic which Portugal colonized and which speaks her tongue, something useful was accomplished by the trip. The aviators demonstrated the accuracy of flight and the inaccuracy of landing methods. It was, as usual, easier to sail than to come to earth. But if Louis Brennan has perfected the helicopter the problems of landing will soon disappear from aviation.—*Editorial in N. Y. Herald.*

The Flying Contrabandist

THE forced landing near Croton-on-Hudson of an aeroplane carrying whiskey from Canada, with the escape of the pilot in a waiting automobile, makes a story of unusual interest. A bootlegging airship has not been reported before, but it doesn't follow that it is a novelty to the illicit trade in rum. Fiction has surrounded the smuggler with an atmosphere of romance, mainly because he must be daring and his occupation involves him in bodily risk. There would be a gap in literature if the contrabandist were left out. Such was the unknown from Montreal, who seems to have arrived at the rendezvous too late to transfer his prize to the "agents," and had to plane down to an inhospitable hill, where he came to grief with a crash that involved most of his consignment.

This fashion of scorning the Mullan-Gage law of the State of New York is not likely to be a success at present. The exhaust of an aeroplane and the whir of the propellers make too much noise, and everybody follows the flight of a strange ship with curious eye. The aeroplane is still a spectacle. In this case mounted troopers of the State came in hot haste to the wreck to seize the contraband and nab the lawbreaker. It might have been hard to empanel a jury to convict him if he had been apprehended. In course of time there must be a State police driving aeroplanes as well as riding horses. Then suspicious planes will be "held up" or followed by "traffic cops" lying along aerial routes connecting such cities as Montreal and New York.

In that day there will be an air code as thick as a volume of the Supreme Court reports. Flying will be strictly regulated, and there will be aerodromes very few miles, with lighthouses at night. Planes will carry numbers to identify them, and they will be darting in all directions, carrying passengers and perishable freight. Rogues, as well as honest men, will be in the air, and the flying police will often have difficulty in distinguishing them. The automobile long ago became a vehicle useful in crime, and the aeroplane will also be. All kinds of portable, ill-gotten goods will be coursing through the air, and thieftaking will become more of a problem than ever.

Flying cannot be regulated too soon for the protection of the public. Commercial aviation is developing rapidly. With better safeguards for passengers, more of them are traveling through the sky. Air limousines now fly thousands of miles without accident. Merchants who want a new market are patronizing the air-carriers. Spring fruits and vegetables can be delivered fresh hundreds of miles away. Mullica, down in sandy South New Jersey, is planning to ship asparagus by plane to Boston every afternoon. But the bootlegger will certainly use the plane to carry his outlawed goods.—*Editorial in N. Y. Times.*

THE NEWS OF THE WEEK

Portuguese Aviators Cross the Atlantic

PERNAMBUCO, Brazil—The Portuguese naval aviators, Captains Sacadura and Coutinho, arrived here shortly after noon June 5, having flown in their hydro-aeroplane from Fernando Noronha, thus completing their transatlantic flight of more than four thousand miles from Lisbon.

The aviators were greeted with a monster reception as they landed in the harbor. At least one hundred large boats and many smaller craft belonging to athletic societies and rowing clubs went out to meet them. Before coming down the aviators took a flight over the city.

The whole population was delirious with excitement. All ships at anchor sounded their whistles, church bells were rung, automobiles honked their horns and factories blew their whistles—all in one deafening medley.

In spite of the rain, the streets of the city were thronged, and all business was stopped for the day. The three-mile quay was crowded from one end to the other. The population staged a parade as the aviators came ashore.

The program of receptions and festivities which had been planned were cut short, because the aviators plan to continue their flight to Rio de Janeiro.

The aviators used three aeroplanes in their flight, which began in April. Two of them were badly damaged in landings, and the time required to ship new planes from Lisbon occasioned the delay in reaching South America.

The flight from Lisbon to Brazil by Captains Sacadura and Coutinho demonstrated, as intended, "the practical efficiency of the new methods of air navigation," Viscount d'Alte, Portuguese Minister in Washington declared in a statement issued when informed by The Associated Press of the success of the venture.

It was also their purpose, he said, to prove the accuracy of instruments recently devised by the aviators. Among these, he said, was a modified type of sextant which permitted the flyers to take observations without recourse to the sea level horizon and a modified sextant used as a "route corrector" while the machine was in flight. The efficacy of the new instruments was declared to have been established by the "remarkable precision of the flight just completed."

Flier to Join Amundsen

Seattle.—Lieut. G. L. Fullerton, Canadian flier, is in Seattle from Ottawa to join the Amundsen expedition to the North Pole.

Lieut. Fullerton has had extensive experience in flying in northern climates and will go ahead by plane to map out the course of the exploration ship Maud, and to make meteorological observations.

Spokane News

A verdict for $2,000 and costs was brought in by a jury in the damage suit of the Yakima Aviation Company against R. E. Hull for insurance on an aeroplane after a trial lasting two days. The jury was out hut a short time. The plaintiff sued for $3,000, the amount of the coverage which, according to evidence, he had been assured was provided, while the defense introduced witnesses in an effort to prove that the plane was not worth that much when the insurance was placed.

Leaving Walla Walla at 9:15 a. m. in two army aeroplanes, bound for Spokane via Lewiston and Pullman, Lieutenants Ned Schramm and H. C. Minter reached this city at 11:30 o'clock and spoke at the noon luncheon of the military affairs committee of the Chamber of Commerce.

The army pilots drove their machines more than 160 miles in 2 hours and 15 minutes. The planes, after circling the city, landed at the Parkwater aviation field, where C. H. Messer, local aviator, met the officer pilots. Staff Sergeant Charles A. Datto and John E. Gordon are accompanying the two lieutenants on the trips as mechanics.

The Glenn L. Martin Flying Field

The Glenn L. Mart'n factory and flying field, shown in cover illustration this week, is located about seven miles from the center of Cleveland in the eastern section of the city. Situated between the main lines of the New York Central and Nickel Plate railroads and one mile from the lake front, it is readily located from the air. An easily distinguished landmark is the New York Central freight yards, partially shown in the right foreground of the photograph.

This field is open to commercial and civilian flyers and adequate ground service is always available. Underground tanks with a capacity of 2,000 gallons of high-test gasoline provides for any contingency.

The field is L-shaped and contains seventy acres. The main landing course, cinder-covered, is 1,900 feet long and always in good condition, being used daily by the Transcontinental Air Mail Service whose hangars and Cleveland headquarters are also located on the field. Weather reports are available through Navy Radio Station NRH, operated from the Company's field.

Other general information is as follows: Latitude, N. 41° 30'; Longitude, W. 81° 42'; Altitude, 762 feet; Average yearly rainfall, 34.24 inches; Average visibility, fair.

General Classification of Instruments and Problems, including Bibliograpby

This report (No. 125) by Mayo D. Hersey of the National Advisory Committee for Aeronautics is intended as a technical introduction to the series of reports on aeronautic instruments. It presents a discussion of those subjects which are common to all instruments. In the first place, a general classification is given, embracing all types of instruments used in aeronautics. The arrangement of information dealing with these various instruments throughout the reports is then briefly indicated as a guide to the reader. Finally a classification is given of the various problems confronted by the instrument expert and investigator. In this way the following groups of problems are brought up for ocnsidcration: First, problems of mechanical design; second, human factor; third, manufacturing problems; fourth, supply and selection of instruments; fifth, problems concerning the technique of testing; sixth, problems of installation; seventh, problems concerning the use of instruments; eighth, problems of maintenance; ninth, physical research problems. This enumeration of problems which are common to instruments in general serves to indicate the different points of view which should be kept freshly in mind in approaching the study of any particular instrument.

A copy of Report No. 125 may be obtained upon request from the National Advisory Committee for Aeronautics, Washington, D. C.

Lights For Night Flights of New York-Chicago Mail

Second Assistant Postmaster General Henderson, who has charge of the air mail servicc, is completing arrangements for establishing a great white way between New York and Chicago to guide night fliers in the mail service.

The Post Office Department has men prospecting the route and arranging to install great beacons not more than twenty-five miles apart. Regular and emergency landing fields, brilliantly lighted, will he installed. Chicago plans the construction of two immense landing fields suitable for night landing.

As soon as the Post Office. Department completes the survey of the night route and has the proper lights in operation a night air mail service will be inaugurated between New York and Chicago to take the place of the present day service.

Postal officials declare the air mail planes by flying at night can carry commercial paper between New York and Chicago in time for the opening of the banks in either city, a saving of one day's interest. It also would prevent embarrassing delays for business houses.

Night flights of air mail planes will be a radical departure for the air mail service. Officials do not intend to have night flying west of Chicago. From Chicago to San Francisco the service will be confined to day flights, for the present at least.

Aeroplane Will Bomb Pests in New Hampshire Forest

Boston.—An attempt to attack forestry pests from the air will be made in New Hampshire by Captain Robert E. Kinlock flying an army aeroplane. From a base to be established at Concord, it was announced today that the flier would circle Gunstock Mountain and other territory in the vicinity of Lake Winnipesaukee, dropping gas bombs as he goes.

The gases are fatal to insect pests, but not harmful to humans or to vegetation, it was said. The flight will be made under the auspices of the Federal Department of Agriculture.

Passenger Service From Knoxville to Elkmont

Aeroplane passenger service will be inaugurated between the Knoxville landing field and the New Appalachian club at Elkmont, acording to announcement made by officials of the Knoxville Aero corporation.

Thirty-minute schedules will be maintained between this city and the summer resort. A landing field is being cleared and the citizens of the Elkmont section will welcome the inauguration of the service. C. A. Griffith and J. G. Ray, manager and pilot of the Airship Knoxville, went to the New Appalachian club grounds yesterday and had a conference with R. S. Homel, in charge.

It has not been announced when the passenger carrying flights will be made to the mountain resort. The aeroplane will climb to an altitude of approximately 4000 feet to make the landing at the club grounds. This will be the first regular passenger-carrying line that has been established between Knoxville and a neighboring resort.

The AIRCRAFT TRADE REVIEW

Limitations on German Aircraft

The limitations placed on the manufacture of aircraft after May 5, 1922, in compliance with the terms set forth in a note in the conference of ambassadors, in Paris, dated April 14, 1922, have just been received by the Automotive Division of the Department of Commerce. They prohibit the building of aeroplanes capable of better than a 3½ four-hour flight, or a distance of more than 600 kilometers. Rigid airships of more than 30,000 cubic meters gas content are likewise forbidden.

The terms laid down in the note from the council of ambassadors, translated from the French by the Automotive Division, are as follows:

(a) Aeroplanes

Article I. A one-seater aeroplane of more than sixty horsepower will be considered a military plane and thus war material.

Article II. An aeroplane capable of flying without a pilot will be considered a military plane.

Article III. Every aeroplane provided with armor plate or other means of protection, facilities for carrying armament of any kind—guns, torpedo bombs—and with aiming devices necessary for them, will be considered a military plane.

The following limits constitute the maximum for air craft heavier than air, and all aeroplanes which exceed these limits will be considered military planes:

Article IV. The maximum altitude at full load, 4,000 meters (a high-compression motor will bring the aeroplane in the military category).

Article V. Speed at full load and at an altitude of 2,000 meters, 170 kilometers (the motor at best efficiency and thus rendering the maximum power).

Article VI. Maximum carrying capacity for oil and fuel (the best quality for aviation use) shall not exceed $\frac{800 \times 170}{V}$ grams per horsepower, V being the speed of the machine at full load and power and at 2,000 meters altitude.

Article VII. An aeroplane capable of carrying a load of more than 600 kilos, a pilot, mechanic and instruments included, although the conditions under articles 4, 5 and 6 are complied with, will be considered a military aeroplane.

(b) Dirigibles

Dirigibles, the cubic content of which exceeds the following, will be considered as military:

1. Rigid dirigibles, 30,000 cubic meters.
2. Semi-rigid dirigibles, 25,000 cubic meters.
3. Non-rigid dirigibles, 200,000 cubic meters.

Article VIII. Factories turning out aircraft shall be registered. All aircraft and pilots, or pilot apprentices, shall be listed in accordance with the conditions provided for in the covenant of October 13, 1919. These lists will be kept at the disposition of the guarantee committee.

Article IX. The stocks of aviation motors, and of spare parts and accessories, shall not be permitted in excess of what will be considered necessary to satisfy the needs of civil aviation. These quantities shall be determined by the guarantee committee.

A revision of the above definitions is contemplated after two years, so that the modifications which the progress of aviation demands may be given consideration.

Personal Par

W. Wallace Kellett, American Representative for H. & M. Farman, has left for the Farman factory in Paris, France. While in Europe, Mr. Kellett will also travel over most of the European Airlines, observing the organization and studying the equipment. His Paris address is care of Morgan Harjes & Company, 14 Place Vendome, Paris, France.

Future Airships Wholly of Metal

In the opinion of Herman T. Kraft, chief aeronautical engineer of the Goodyear Tire and Rubber Company, the airship of the future will be of all-metal construction. This method, he believed, will be of fundamental assistance in the development of dirigibles for worldwide commercial use in aerial transportation. Two factors, it is pointed out, must be considered above all others in the construction of airships of any kind, namely, safety and durability. There must be absolute protection against structural failures as well as against fires. As long as airships are constructed of inflammable materials there will always be some danger of fire, especially with the use of hydrogen gas.

"Uniform distribution of strength," says Mr. Kraft, "which is the major basis of safety, is exceedingly difficult to obtain, even in a rigid airship, because of the very complicated calculations necessary to be sure of safety, since we have to figure unknown factors and allow for them in every airship we build. It will be possible with an all-metal ship to make those calculations much more exact than has hitherto been possible, due to the reduction of the number of small riveted parts, which have formerly been multitudinous.

"The entire surface of the ship will be of metal, thereby assuring greater durability and reduction of fire hazard. Tests have been made which indicate that even hydrogen ignited on the surface of an all-metal container will burn freely without heating up the metal, so that there would be no danger of the envelope being consumed by the flame.

"Unquestionably, the building of such a ship would be a mammoth undertaking, but with the present engineering knowledge available its construction would be entirely practicable. Indeed, it has been attempted before, so far back as two decades ago, and flights were actually made with an all-metal ship with conical ends and cylindrical body, but the ship was not a success, chiefly because engineering knowledge had not progressed sufficiently in aeronautics and proper construction materials were not available."

Mr. Kraft states that aluminum sheeting would doubtless be the metal employed, with strips of very flexible non-inflammable material or wire lacing interposed at various points to take care of the flexing of the envelope while in flight. He also considers that approximately 1,000,000 cubic feet capacity, with a theorctical length of 350 feet and a maximum diameter of about 75 feet, would be the proper size of ship to make to prove its practicability.

"In any consideration of all-metal airships," adds Mr. Kraft, "the question of gas-tight seams has generally been a bugbear, but it has now been conclusively proved that the seams in such a ship can be made gas-tight, especially in a container carrying low pressures. The actual building would be somewhat of a problem, but by using airbags to keep lifting the ship progressively while under construction, and erecting superstructures in the hangars the riveting, lacing and assembling could easily be handled. The rigidity of the structure which would have some degree of flexibility, would eliminate many of the structural difficulties in rigid airships of the present design.

"The first practical all-metal ship will be the key which opens the gates, hitherto barred because of lack of positive assurance of safety and durability, to a real commercial use of the dirigible in air transportation. A striking characteristic of our day is the rapidity with which people accept the marvelous inventions which but yesterday seemed to be the delusions of cranks. We have long ceased to wonder at radio and accept without question every news story of its possibilities. There is every indication that it will be the same with aeronautics with the advent of the first practical all-metal airship, which can be assembled with greater speed.

"Undoubtedly a ship of the construction features pointed out, would practically abolish the dangers from fire and structural breaks, and have all the safety of a modern ocean liner."

Pacific Marine Airways

The Pacific Marine Airways operating H.S.2L. open cockpit 6-passenger seaplanes, are now in active service (commercially), flying from San Francisco Bay. The moorings of the Company are at the Marrina at the foot of Laguna St., San Francisco. The officers of the company are: C. T. Eastman, Pres. and Gen'l. Manager (late Lt. U. S. Air Service; L. Blackner, Secretary and Treasurer and Ron J. Smith, Chief Pilot (late Flying Officer, R. A. F.). The company conducts sight-seeing flights to any desired place over water and instructs in marine flying.

THE WRIGHT DIRIGIBLE ENGINE AND ITS DEVELOPMENT FOR THE NAVY

By GEORGE J. MEAD

Chief Engineer, Wright Aeronautical Corporation

NOW that the war is over, the general public is apt to forget that preparations for future wars are still a necessity, and that those responsible for the protection of our country are continually working along these lines. In laying out the future development program for the Navy, it was deemed advisable to learn first hand about the advantages of dirigible ships for military purposes. Up to this time our Government had not owned any dirigible ships, and none had been built in this country. The Germans, however, principally through the efforts of the Zeppelin Company, had done a great deal of work with this class of ship, having flown commercially, carrying large numbers of passengers, prior to the war, and some of these same ships were used to bomb England during the war.

The Germans' work left no doubt that the dirigible was practical for certain purposes, particularly long distance flights, such, for example, as one accomplished by the Germans during the war, when a ship was sent to Africa with supplies for some of their troops cut off from communication with the outside world. This ship, upon its arrival at its destination, found the troops captured by the Allies, and, therefore, had to fly back to Germany without landing. This was probably one of the longest single flights that has ever been made. The total mileage covered was in the neighborhood of 4,000 miles.

The American program included the construction of a large hangar at Lakehurst, N. J., and the purchasing of one ship from England, called the ZR-2, and the construction of a similar but somewhat larger ship in this country, by the Navy.

With this program in mind, it was next in order to start the development of some American engines to propel these ships. It so happened that our Company had been considering the advisability of developing this type of engine, and had carefully studied the matter. As a part of this investigation, a single cylinder engine was constructed for the purpose of testing the cylinder construction, which we proposed to use. After carefully reviewing the results of our single cylinder tests and the preliminary design of the proposed dirigible engine, the Navy gave our Company a development contract for three of these engines. This contract was received last June, and it is believed that we have set a record in engine construction by completing the 50-hour test on this engine on March 20, 1922, which meant that the Engineering Department designed the engine, the Experimental Machine Shop built it, and the Dynamometer Room tested it, all within nine months.

About the same time, the Navy Department placed an order with another company for the development of a six-cylinder 300 h.p. dirigible engine. Since this engine was practically identical in size to the Maybach, there was very little doubt that trouble would be experienced in securing a satisfactory engine. In this way, the Navy encouraged the development of two American dirigible engines.

It is perhaps interesting to note how we came to the conclusions, which were reached, in regard to the engine design. The German practice, naturally, was the most modern, and to it we turned in studying the problem. It seemed that the type of engine which they had evolved was a straightforward six-cylinder type, with individual cylinders, the whole construction being simple and durable. These engines were run at comparatively slow speeds, usually between 1200 r.p.m. and 1400 r.p.m. The largest German dirigible engine used during the war, of which we have any knowledge, was the Maybach, which was a 300-h.p. engine, having cylinders approximately 6½ x 7 inches. This engine weighed 921 lbs., or 3.25 lbs. per B.H.P. It is understood that larger engines were being developed, but were not used in service. Since the large dirigibles required considerable power, it had heretofore been necessary to use a number of what are popularly known as "Power-Eggs," or Nacelles, each one carrying an engine. Since the maximum unit powers available were small, there were of necessity a considerable number of Nacelles, each one of which had to have an engineer. This division of power resulted in considerable unnecessary complication and weight. For that reason, it seemed most advisable to endeavor to develop as large a single unit of power as could be safely undertaken with the reasonable assurance of success. Otherwise, we were simply copying what the Germans had done and not developing anything of particular value. This simplified the problem to one of how large a bore was it wise to use.

After a careful consideration of the successful large engines of high power output, it was decided that a 7-inch bore would be reasonably safe, and with an 8-inch stroke we would have an engine capable of developing 400 h.p. at 1400 r.p.m. With such large cylinders, the problem of proper valve and piston cooling became pre-eminent. Very careful design work resulted in developing a cylinder in which the valve cooling was practically ideal, and by the use of a properly proportioned aluminum piston the piston cooling problem was equally well solved. Tests of a single cylinder of this construction showed that it was readily possible to secure a total of 400 h.p. from the completed engine.

The photograph of the engine which accompanies this article gives a very good idea of its general construction. As can be seen from the photograph, the engine is of the six-cylinder, vertical, water-cooled type, with individual cylinders. As already has been mentioned, the bore is 7 inches and the stroke 8 inches, which gives the engine a displacement of 1850 cu. ins. The contract weight for the engine was 1400 lbs., but the engine actually weighs 1320 lbs., which results in a weight of 3.30 lbs. per h.p. Each cylinder is built up with a cast-iron head, to which is attached a steel barrel and water jacket. There are four valves per cylinder, two inlets and two exhausts. These are operated by push rods from camshafts carried in the crankcase, the push rods in turn operating rocker arms, which are mounted on smaller roller bearings. The pistons are aluminum and have 4 compression rings and an oil scraper ring. The connecting rods are tubular in section and have 4 bolts at the big end and a 1¾-inch floating wrist pin bearing in a bronze bushing at the upper end. The crankshaft is a 3-inch diameter shaft, with a bearing on each side of each crank throw. The crankcase is a very deep section aluminum casting, the shaft being supported in the upper case by bearing caps, which are held in position by the through bolts which hold down the cylinders. The case is supported on the bed timbers by extending the double walls of each main bearing through the sides of the case in a box section, the space between the two walls being cored out to provide for the passage of air across and around the main bearings, for cooling purposes. The lower crankcase is made in two sections, and forms an oil sump. These sections are independent of one another and can be removed for inspection purposes. The carburetion is taken care of by two NA-S8 carburetors, made by the Stromberg Motor Devices Co., and each carburetor is attached to an inlet manifold supplying three cylinders. The ignition is supplied by two two-spark six-cylinder Simms magnetos, located at the rear of the engine, firing four spark plugs per cylinder. The lubrication system is full pressure throughout, and oil is pumped directly to all the main bearings, crankpins and wrist pins. The cooling system consists of a large water pump located at the center of the engine, which delivers water across the heads of the cylinders, there being a water outlet at each end of the engine to the radiator. To facilitate the control of the engine, the throttles and instruments are grouped on a control panel at the rear. It will be noticed in the photograph that the oil pumps, oil strainer, oil relief valve and magnetos are located just behind and below the control panel, so that the engineer has practically all the parts requiring attention within easy reach.

The prime requisite of this engine, of course, was durability. It must run long periods without attention. Moreover, should attention be required, the design had to be such that each part was readily accessible without disturbing the other parts. To carry out this idea, individual cylinders were used, and it is, therefore, possible to remove any one of the 6 cylinders. The connecting rods can be taken off the shaft with the engine in position in a Nacelle, so that it is practically possible to inspect and overhaul the engine without removing it from the ship.

We can all be proud of the record which this engine established on its Acceptance Tests. To begin with, it was given an hour's running, one-half hour of which it developed 350 h.p. at 1350 r.p.m., and one-half hour 400 h.p. at 1400 r.p.m. This test was known as the Acceptance Test, and was followed by a 50-hour run of more than usual severity. Forty hours of this run the engine was operated at 1350 r.p.m., developing 350 h.p., and for 10 hours the engine developed 400 h.p. at 1400 r.p.m. No difficulty was experienced in completing this test satisfactorily, and a very unusual record for fuel and oil consumption was es-

Digitized by Google

tablished. The average fuel consumption for the whole 50 hours was .475 lbs. per h.p. hour, and the average oil consumption was .008 lbs. per h.p. hour.

Briefly, the Wright Company has succeeded in developing a larger engine than had been used for this service anywhere else in the world in the record time of 9 months, and has made a very satisfactory job out of the first experimental engine. A few very minor modifications were found necessary by these tests to make the succeeding engines entirely satisfactory for their intended work.

The history of this engine is doubly interesting, owing to the fact that it shows in general our procedure in developing a new type. The first step in connection with each new model is to determine the requirements, such as the power, weight and any particular requisites, such as in this case, durability. With this in mind, we endeavor to investigate the cylinder design by building an experimental cylinder and testing it thoroughly. After a cylinder has been satisfactorily developed the final design of the complete engine is undertaken. Following the completion of the design of the engine an experimental model is built in the Experimental Shop and thoroughly tested and developed, so that the following engines of this model produced by the Company incorporate any modifications found necessary in the original design, thus making succeeding engines entirely satisfactory power plants.

In passing, it should be noted that we have established what is probably a new precedent for aeronautical work, in so far as the development of new types of engines go, and that is, that we retain the right to decide whether or not the particular engine which we build satisfies the conditions set up for it. In other words, if, after an engine has been built and tested, we do not feel that it is satisfactory for the service for which it is intended, we will not deliver the engine. What we are trying to sell is the best engine that can be made for each particular service, and we stand behind each engine with a guarantee of satisfactory service. Heretofore most new engines were built for a price, with no particular guarantee as to their performance. The purchaser took a chance on each one. It is not so with Wright engines, as we guarantee a predetermined performance.

Naturally the question arises as to the feasibility of dirigible ships, having so freshly in mind the recent disasters with the ZR-2 and the Roma. Unfortunately, all new engineering work entails a considerable amount of experimental development. It is that period through which we are passing now in the development of dirigible ships. Just as with submarine development work, we are bound to have a certain number of accidents resulting in the loss of life, so it is with airship development work. It is believed that from the experience gained from these two accidents, which were thoroughly and carefully investigated, future disasters of this kind will be eliminated. The successful development of airships of this type will place us in an enviable position as far as air supremacy of the world is concerned. It is, for this reason, worth while to make every effort to thoroughly develop airships, if this is at all possible, and it certainly seems so.

COOLING SYSTEM TEST OF LE PERE P-70 EQUIPPED WITH SIDE RADIATORS

Object of Test

To determine the cooling requirements of the U. S. A. "12" (Liberty) engine when using side radiator.

SUMMARY

The U. S. A. "12" engine rated at 400 horsepower requires 0.625 square feet of cooling surface per rated horsepower for an operating difference of 63° C. between the air temperature and the mean temperature of the engine jacket water. This applies when free air radiators are mounted on the sides of the fuselage and in the propeller slip stream of an aeroplane, climbing at 70 miles per hour and using the U. S. A. "12" engine turning 1,500 revolutions per minute. During level flight at 126 miles per hour and 1,720 revolutions per minute, a temperature difference of 48° C. is obtained with this surface. A temperature difference of 63° C. at 6,000 feet with free air radiators will usually allow full climb at full throttle in ground temperatures of approximately 95° F.

Date and Place of Tests

The tests were conducted June 30 and July 1, 1921, by the Engineering Division of the Air Service under the direction of the Cooling Systems Branch of the Power Plant Section.

General Description

The aeroplane used was a LePere two-seater fighter, Model U. S. A. C. "11," McCook Field No. P-70.

The installation tested is known as the "closed-type" cooling system; that is, it is equipped with a safety valve which prevents overflow until a certain pressure is reached. The cooling system consists of two radiators, one set of shutters for each radiator, shutter controls, an expansion tank, safety valve, and the necessary piping. Complete drawings of the system are listed in Parts List, pages 6271 to 6274, inclusive, 6282 to 6284, inclusive, 6477 to 6480, inclusive, and 6508 to 6518, inclusive.

The radiators are installed, one on each side of the fuselage to the rear of the engine with their front faces perpendicular to the air stream. (See figures 1 and 2.) Their dimensions, determined from actual measurement, are as follows:

Height (over all)	24 ins.
Width (over all)	10¼ ins.
Weight empty (including shutter)	60.5 lbs.
Weight water capacity	27 lbs.
Core height	20 ins.
Core width	10 ins.
Core frontal area each radiator	1.39 sq. ft.
Cooling surface per square feet frontal area of core	90 sq. ft.
Cooling surface each radiator	125 sq. ft.
Total cooling surface both radiators	250 sq. ft.
Cooling surface per h.p. at 400 h.p.	0.625 sq. ft. per h.p.

The radiator core is the U. S. standard type, made of seamless round copper tubes, 9 inches long, with expanded hexagonal ends, corresponding to A. S. drawings Nos. M-1318 and M-1337.

The radiators are bolted to the fuselage through shock-absorbing rubber pads and steel brackets.

The shutters are of the vertical vane type and consist of six vanes for each radiator. The vanes have a stream-line form, as shown in A. S. drawing X-29304. They are 2 inches wide by 19⅞ inches long. An attempt was made to decrease the head resistance of the radiators when the shutters were closed by slanting them, so that the plane of the closed shutters makes an angle of 30° with the face of the radiator. The slip stream is therefore deflected 60° instead of 90°, as would be the case if the shutter were parallel to the radiator face.

The shutters are controlled by push rods and bell cranks connecting to a conventional type control lever in the cockpit.

The expansion tank is mounted on the leading edge of the top wing center section. It conforms to drawing No. X-29573. Its weight and capacity are as follows:

Fig. 1

Fig. 2

Digitized by Google

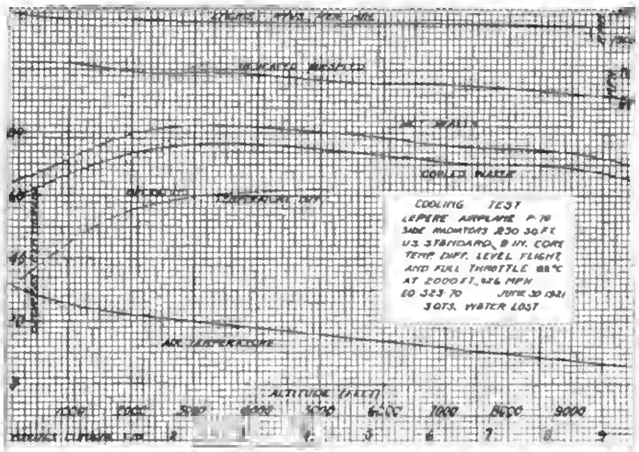

Fig. 3

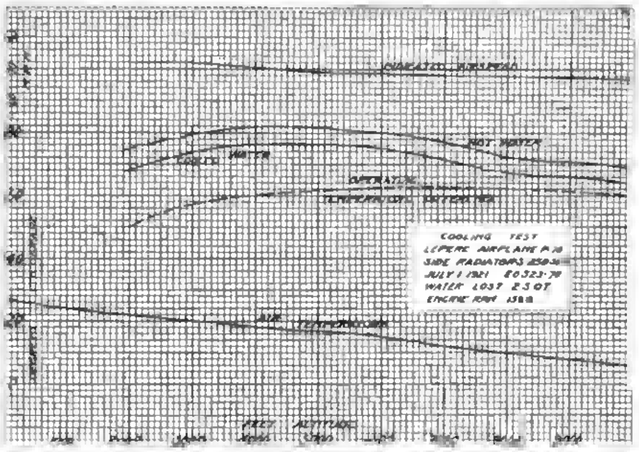

Fig. 4

Weight expansion tank empty.............. 13 pounds
Weight full of water....................... 38 pounds
Water capacity .... 3 gallons

A filler neck and cap of stream-line form is fitted to the expansion tank. Two Lunkenheimer air-pressure relief valves are provided in this cap to allow the water to overflow when a pressure of 3 pounds per square inch is reached. The water which overflows through the relief valves is carried through a ⅜-inch diameter overflow pipe to a convenient point at the side of the fuselage, where it is discharged.

The water piping is arranged so that water leaving the top of the engine goes to the expansion tank. Two pipes from this tank direct the water down each front center section strut to the radiators. The water leaving the radiators enters the engine water pump.

The engine exhaust manifolds are arranged to direct the hot exhaust gases away from the radiator.

For the purpose of the test a Boyce distance-reading thermometer, indicating the temperature of the water after it had been cooled by the radiators, was provided, in addition to the thermometer ordinarily supplied to indicate the temperature of the hot water leaving the engine. A strut thermometer was also installed which showed the temperature of the air through which the aeroplane was flying.

Description of Tests and Results

The tests were conducted in the usual manner. The aeroplane was flown at full throttle and full climb until positive cooling of the water in the system occurred. Full-throttle level flight tests were also made at altitudes of 10,000, 8,000 and 2,000 feet. The data obtained is shown in the following tables:

During the climb it will be seen from the following tables and curves (Figs. 3 and 4) that the maximum temperature of the water was reached at an altitude of approximately 4,000 feet. The maximum difference between the air temperature and the mean temperature of the jacket water was reached at approximately 6,000 feet and was 63° C. During level flight at 2,000 feet the difference between the air temperature and the mean temperature of the water in the engine was 48° C.

This performance normally allows full climb at full throttle, without boiling the water in the cooling system, with maximum ground temperatures of approximately 35° C. to 40° C. or 95° F. to 105° F., when the rate of temperature decrease with altitude is equal to that occurring during these tests. This is satisfactory according to Air Service requirements. It will also allow full-throttle level flight at 2,000 feet altitude without boiling, when the ground temperature is 45° C. or 112° F.

It is to be noted that the maximum operating temperature difference in each of the climbs was practically the same; that is, 63° C. It does not follow that the maximum ground temperature at which the aeroplane can be climbed without boiling is also a constant figure. If the hot-water temperature at the time of take-off had been 95° C. on either of these tests, instead of approximately 62° C., the maximum ground temperature in which full throttle full climb could be made would have been 29° C. or 85° F.

Assuming 6° C. temperature drop between water entering and leaving radiator

$$\frac{95 + 89}{2} = 92° \text{ C. mean jacket water temperature.}$$

92 — 63 = 29° C. or 85° F. maximum allowable ground temperature.

The maximum allowable ground temperature is also affected by the rate of temperature decrease with altitude.

The surface per horsepower furnished is $\frac{250}{385} = 0.65$ square foot per horsepower, based on 385 horsepower and 70 miles per hour air speed during climb at 1,560 revolutions per minute of the engine. This applies when the free air radiators, using the U. S. standard 9-inch core, are used and when the air-flow conditions are similar to those occurring on the aeroplane tested. Based on the rated horsepower of 400, the surface provided is 0.625 square foot per horsepower.

The water-flow capacity of the radiators was tested. A curve of the results is shown in Fig. 5. This is satisfactory and exceeds the requirements of the engine.

The shutters are very effective and allow a wide range of temperature control. The effect on the aeroplane performance of slanting the plane of the closed shutters toward the fuselage is not known.

Cooling Test on LePere P-70

Date, June 30, 1921. Hour, a. m. E. O. No., 523-70.

COMMERCIAL AVIATION

[*The following article is an excerpt from the 1922 Aircraft Year Book shortly to be published by the Aeronautical Chamber of Commerce of America.*]

IN aviation the year 1921 is marked by three outstanding events, one of universal and epochal importance.

During June and July there were held, 100 miles off the Virginia Capes, a series of experiments in the course of which aircraft flown from land bases, bombed and sank, one after the other, a submarine, destroyer, light cruiser and dreadnought, the most modern examples of warship construction.

In the fall the Conference on the Limitation of Armament was held in Washington, and it was asserted that the bombing tests cleared the way, more than any other single event, for a possible solution of the international competition in capital ship construction. For the 2,000-pound TNT bomb which crushed in the steel walls of the "Ostfriesland" was, as the Army Chief of Ordnance remarked at the moment, "heard around the world."

Commercial aviation, struggling for nearly three years without assistance of a national policy, found an intelligent and sympathetic friend in the Harding administration. The President in his inaugural address urged the early enactment of an Aerial Code and the consistent encouragement of civilian flying. In consequence there was drafted a bill regulating the operation of aircraft in interstate and foreign commerce; and establishing a Bureau of Civilian Aeronautics in the Department of Commerce. This bill, introduced by Senator Wadsworth, passed the Senate, and at the time of publication of this volume was before the House Committee on Interstate and Foreign Commerce.

Possibly the most definite proof of growth in interest in commercial aviation was the establishment, late in the year, of the Aeronautical Chamber of Commerce of America. The need for such an organization had long been felt. With definite assurance that an Aerial Code would shortly be established, manufacturers of heavier- and lighter-than-air craft, motors, parts, accessories, materials and supplies; dealers, distributors, operators and owners; associations, corporations, firms and individuals engaged in the commercial phases of the art, decided to equip themselves with a national organization of the type which had proved so useful in the development of other American industries.

The Aeronautical Chamber of Commerce was incorporated under the laws of the State of New York "to foster, advance, promulgate and promote" aeronautics, and "generally to do every act and thing which may be necessary and proper for the advancement" of American aviation. Formal organization was announced on December 31, 1921, with a charter membership of 100. At the time of publication membership had increased to 175, including such pioneers as Orville Wright and Glenn H. Curtiss, and embracing practically every important aircraft manufacturing unit in the United States.

Commercial aircraft in 1921 definitely began the demonstration of practical utility. The business man who, in 1919, was merely curious, and in 1920 was interested, became convinced, in 1921, that aerial transport was no longer fancy but fact. More miles were flown, more paid passengers booked and more package freight and goods carried.

Comparative Commercial Aircraft Operations, 1920-1921

	1920	1921
Estimated number of aircraft in operation	1,000	1 200
Estimated total mileage	6,000,000	6,250,000–6,500,000
Operating companies reporting	88	125
Equipment of these companies	365–425	500–600
Mileage flown by these companies	3,136,550	*2,907,245
Number of passengers carried	115,163	122,512
Pounds of freight carried	41,390	123,227
Number of flights by operating companies	Unknown	130,736
Average duration of flights	Unknown	21 minutes
Average charge for short flights	$12.50	$9.00
Average charge per mile for inter-city flights	.65	.55
Average charge per pound for freight	Unknown	.55
States in which operations were carried on	32	34
Air terminal facilities	128	146

The foregoing is believed by the Aeronautical Chamber of Commerce to be accurate. The census of craft, in the absence of Federal law requiring registration, is based upon the statements of 125 established operators, upon Air Service and Naval Estimates, and upon the personal observations of representatives of the Chamber throughout the country. The 1,200 craft in operation represent an increase of 20 per cent over the figures for 1920, and, generally speaking, this percentage of increase is noted throughout.

Approximately one-half the equipment was controlled by established organizations, the other half being in the hands of the gypsy flier, the care-free and often too-careless itinerant, whose wanderings from Coast to Coast and from Mexico to Alaska, have done a certain amount of good but probably much more harm. It being known that the operators at fixed points covered approximately 3,000,000 miles, carrying about 122,500 passengers, it is estimated that, all told, rather more than 250,000 persons flew and that, counting the wanderings of the gypsy, 6,500,000 miles were compassed by commercial aircraft during the year.

The most valuable service which aircraft provide is speed. Conjoined with this is their unique ability to operate independently of land of water, dominating both in time of war, and capable of adaptation in time of peace to a multitude of novel uses limited only by ingenuity and commercial and industrial needs.

The following visualizes the service of the airplane and airship:

National:—National Defense (Army, Navy, Marine Corps) Air Mail; Forest Patrol; Coast Guard; Customs and Revenue Service; Agricultural Survey; Coast and Geodetic Survey; Scientific Observation; Warning and Relief in Disaster.

Civic:—City Planning; Road and Building Construction; Rail and Water terminal problems; Fire and Police Zoning; Park Improvement.

Commercial:—Passenger Service; Freight Transportation; Messenger Service in Banking; Surveying—Engineering; Aerial Photography; Collection and dissemination of News; Advertising and Publicity; Sport and Pleasure; Commuting.

"Commerce Demands Speed; Flying is the Answer," is the timely and more original trade phrase being urged by the operators. "Less Waste, More Speed," is the reply which Commerce makes, through Samuel M. Felton, president of the Chicago Great Western Railroad, and during the war Director-General of Transportation for the A. E. F.

The aeroplane man, alive to what is undoubtedly the most vexing of all contemporary business problems, conceives the greatest commercial need to be swifter dispatch. The railroad man, equally conscious of the need, but schooled with practical experience, demands economy. This is the challenge to commercial aircraft and it is significant of the immediate future that, in 1921, improvement in construction, decrease in operating costs and increase in the factor of safety and reliability, went far toward establishing the commercial aerial transportation business upon a sound financial basis, with but one thing lacking, and that about to be provided—the enactment by Congress of an Aerial Code.

Commerce is the same in principle, whether carried on in a thickly populated territory, well equipped with the most improved means of transportation, or whether in sparse regions poorly served, if at all, by conveyances on road, rail and water. Commerce is satisfactory only when conducted with dispatch, and there are circumstances and conditions under which commerce will gladly pay an increased tariff for increased speed.

The correctness of this statement is apparent upon the analysis of the following table showing aircraft operations by states:—

State	1920	1921	Increase	Decrease
Alabama	1	0	—	1
California	8	10	2	—
Colorado	3	1	—	2
Connecticut	1	1	—	—
Florida	3	3	—	—

States Showing Increase in Operations—22
(Note:—Canada reported in 1920 but not in 1921).

The greatest growth in commercial aerial transport has been in those parts of the country where the volume of traffic requiring rapid transit is such as to choke available surface facilities or where, surface facilities being antiquated, available traffic seeks other means of movement. In both cases Commerce willingly pays a premium.

The table showing operations by states illustrates that the pressure upon surface facilities in Illinois, Massachusetts, New Jersey, New York, Pennsylvania, etc., has encouraged the establishment of eighteen new aircraft operators, all of which engage in occasional transport between cities, but which are handicapped in their endeavors to establish regular service, by the absence of landing facilities, properly disseminated weather reports, and Aerial Law which is primary to the legitimate general capitalization.

In California, Idaho, Iowa, Kansas, Kentucky, Maine, Missouri, Montana, Nebraska, Nevada, North Dakota, Oklahoma, South Carolina, South Dakota, Texas, Virginia, and West Virginia, where distances are great and surface facilities backward, commerce is willing to utilize aircraft. For the same service which appeals to the great business establishments of New York or Chicago, eager to hasten delivery and speed collection, appeals likewise to the small community the progress of which manifestly rests upon the rapidity with which it releases itself from isolation and establishes quick contact with purchasing territory hitherto unattainable.

STANDARDIZATION AND AERODYNAMICS

By E. B. WOLFF

Director Rijks-Stodienst voor de Luchtvaart, Amsterdam, Nederland

The discussion brought up by William Knight in The Aerial Age of June 20th, 1921, on "Standardization and Aerodynamics" has given rise to a very interesting expression of the views on this subject of the most important aerodynamical laboratories in Europe (see previous issues of Aerial Age, article by Prof. Prandtl, October 3rd, 1921; article by Prof. von Karman, January 2nd, 1922; article by Col. Costanzi, February 20th, 1922; article by W. Margoulis, March 6th, 1922; article by Col. Verduzio, April 3rd, 1922; and article by Dr. Katzmayr, May 8th, 1922). I think I should state what is the stand taken by the Rijks-Studiedienst voor de Luchtvaart on the matter of Standardization of graphical methods of representation of results of tests made in aerodynamical laboratories, standardization of symbols and coefficients used in technical aeronautical publications in various countries, etc.

The desirability of reaching an international agreement on this very important matter, as suggested by Wm. Knight, has already been voiced in The Aerial Age by eminent scientists and aeronautical experts and, in my estimation, as well as in the estimation of Dr. C. Koning and Dr. A. G. Baumbauer of the Section for Aerodynamical Tests of our Institute, we must express our solidarity with the idea of international scientific cooperation in aeronautics which has been championed by Wm. Knight, with whom we have already discussed several times this matter during the last few years while he was the Technical Assistant in Europe to the U. S. National Advisory Committee for Aeronautics.

It seems to us that it should not be difficult to come to an agreement on this point, as the importance of standardization in aerodynamics will be granted by all aerodynamical experts and the change from the system originally used by a laboratory to the one that will be adopted as the international standard system will not offer serious difficulties. Moreover, a discussion on these questions may be a welcome introduction to further international cooperation and understanding. An aerodynamical coefficient which stands at the present time in great need of standardization is the coefficient *vl* (Reynolds' number) for model tests. Considering the diameter and the maximum velocity of the existing wind tunnels, it would perhaps be possible to divide them in groups, each group making routine-tests at the same value of *vl* (such as tests on wing sections and aeroplane-models) in order to make the results of these tests comparable with each other, without any corrections for scale-effect.

TABLE I

Wind Tunnel	V in M/sec	D in M	VD in M2/sec
N. P. L. 4 ft.	15	1,22	18,3
N. P. L. 3 ft.	21	0,91	19,1
Massachusetts Institute of Technology	29	1,22	35,4
N. P. L. 7 ft. Nr. 1	20	2,13	42,6
N. P. L. 7 ft Nr. 2	26	2,13	55,4
Rijks-Studiedienst voor de Luchtvaart (Holland)	35	1,60	56,0
Eiffel (Auteuil)	30	2,00	60,0
Tokio (Marine)	30	2,00	60,0
Saint Cyr	40	2,00	80,0
McCook Field	235	0,36	84,6
Istituto Sperimentale di Aeronautica (Rome)	50	2,00	100,0
Göttingen	50	2,24	112,0
Luftschiffbau Zeppelin	50	3,00	150,0
Dayton	67	2,50	167,5

In TABLE I the values of V (maximum velocity) in meters per second, those of D (diameter or side of the square of the working portion) in meters, and the product VD are tabulated for some of the existing wind tunnels. The product VD is the deciding factor of the maximum value of *vl* at which tests can be made. This table shows that there are a number of wind tunnels for which the values of VD show only small differences.

Comparative tests in the different wind tunnels is another important aspect of the proposed international cooperation.

Although we have at the time joined Wm. Knight in his effort to bring about a comparison of results of model tests on standard-models in different laboratories, we should like to point out some difficulties which will perhaps make it desirable to introduce some slight changes in the comparative tests program now under consideration when one or two models are successively tested in the wind tunnels of different laboratories, as has been proposed values found for the lift, drag, etc., will not be the same. The question will then arise, what is the reason for the differences and which value must be considered as the true one?

The differences found may be caused by the following factors, which can be arranged under three main headings:

First, there are errors caused by the method of measurement of the forces. Here we must mention the interference of suspension members with the flow past the model, and the correction needed for the forces acting on the parts of the weighing apparatus projecting into the wind stream, and also errors of the weighing apparatus itself and errors due to the instruments used for measuring the air velocity.

Second, the influence of the boundaries of the air-stream upon the results.

Third, the differences which are due to the nature of the air-stream itself—irregularities of the velocity of the air-stream

Digitized by Google

in different parts of the cross section and in regard to time, turbulence of every kind and variations of static pressure. It seems to us that it would be greatly desirable to separate errors caused by these three groups of causes in order to reach a sound comparison of wind tunnel characteristics, and this can be done by pursuing the following experimental program:

1. Experiments on the different methods of suspension of models and a critical study of the different kinds of weighing mechanisms and velocity measuring devices used by the various laboratories.
2. Experments and theoretical investigation of the influence of the finite dimensions of the air-stream.
3. Experiments on the influence of irregularities of the flow and of turbulence around different kinds of models.
4. A thorough exploration of the air-stream of the wind tunnels as to turbulence, regularity of the velocity and variation in static pressure.

The experiments listed under 1, 2 and 3 need not be carried through in every wind tunnel. This part of the work can be done by laboratories, which are best fitted for this work and dispose of different wind tunnels so that their ordinary work is not too much retarded by these long systematic tests. Some of this work has already been done[1]. Only the experiments mentioned under 4 need to be done in every existing wind tunnel.

The results of a comparison of this kind will be that an intimate knowledge will become available of the inherent quality of the air-stream of each laboratory. When, from the tests grouped above under 1, 2 and 3, we shall have learned the influence of the different factors upon the results of the tests, it will be possible to draw conclusions about the exact meaning of such tests.

A program, as set forth above, will necessarily take a great deal of time; but it seems to us that such a program would not be too much of a burden on the laboratories and would lead to a knowledge of the actual conditions under which research work is carried which will be of great help to the progress of the scientific end of aeronautics.

However, it is desirahle to have without further delay some preliminary base of comparison, and for this reason the adoption of a preliminary limited program of investigation as suggested by Wm. Knght would be acceptable to us.

The superintendant of the aerodynamical section of the National Physical Laboratory in Teddington informed us that he is actually experimenting on some models prior to the circulating of them through the different laboratories which are willing to make the necessary experiments, and we are awaiting with interest the materialization of this preliminary form of international cooperation in scientific work, which we hope will become more intimate and effective as the time goes on.

[2] Part of this work has been done, too, we have published our results regarding velocity-distribution in the wind tunnel of the Ryks-Studiedienst voor de Luchtvaart: "Verslagen en Verhandelingen van den Ryks-Studiedienst voor de Luchtvaart", Deel I, 1921, p. 11. We presume that a great deal of unpublished results obtained in other tunnels could be collected.

THE CHOICE OF AIR ROUTES

By EDWARD P. WARNER

Professor of Aeronautics, Massachusetts Institute of Technology*

A CASUAL inspection of the air-travel map of Europe suggests to the layman but little attempt at a careful determination of the location of the routes operated. Criss-crossing back and forth across the continent and seeming to have been laid down haphazard, they give no superficial indication of the application of analysis to their choice.

There are, nevertheless, certain rules with which the location of all commercial air lines should be in accord. Those rules have in general been followed in Europe as they must be followed here, although the peculiar form of some of tbe governmental subsidies has led to the development in the Eastern hemisphere of a few lines whose merit is political rather than economic. Certain countries, for example, offer exceptional inducements for the promotion of lines running from the country to its colonies and dominions.

It is not without significance, and it was not the result of accident, that the three big flights carried out in the last three years by British aircraft have been from the British dominion of Newfoundland to the Irish coast, from London to the British dominion of Australia, and from London to the British dominion of South Africa. It is not without significance also that one of the most notable French cross-country enterprises was the flight of Commandant Vuillemin from Paris to Dakar in French West Africa, crossing French Morocco and the French Sahara on the way. The governments all realize the great possibilities of the aeroplane as a means of accelerating communication and tightening the bond between the mother country and her dominions.

Aeroplanes in India

The air map of Central Europe, too, is somewhat distorted by the provisions of the International Air Navigation Convention, under the terms of which there is no direct aerial communication between the territory of the principal allied powers and that of their late enemies. Travel between Paris and Berlin, for example, must be carried on by way of Amusterdam, changing from a French to a Dutch or German aeroplane at that point.

The political factor in the determination of flight routes may be even more marked within the next few months than it has in the past, for the report comes from Berlin that there are threats from certain German sources of a permanent aerial boycott against the allied powers unless the restrictions on German aircraft construction and traffic are relaxed.

Only by brushing aside such extraneous considerations as these can he arrive at the economic fundamentals of the problem. First among those fundamentals is that the aeroplane with its relatively high costs can compete most effectively with established means of transport where those means of transport are slow, uncertain, or inconvenient. It is for this reason that the aeroplane has come into such extensive use as a regular means of transport for official travelers in certain countries less developed than our own. In Haiti and San Domingo, for example, it is reported that the aeroplane is in regular use by high officials of the American Marine Corps administration in order to get from one part of the islands to another. In the East, similarly, the British have found it invaluable for transport in Palestine and Mesopotamia. In fact, the play in which George Arliss is now appearing in Boston, "Tbe Green Goddess," is based on the events which grew out of such a use of the aeroplane by British officials in India. Where the only previously existing means of travel was by camels or other riding animal tbe aeroplane cuts the time required for a journey by fully 90 per cent. Obviously, under such conditions the advantages of air transport shine brighter than they do when it must compete with the Knickerbocker Limited or the Twentieth Century.

One of the most notable examples of a route which runs through a highly developed country and which connects great centers of industry and population, and on wbich the existing means of transportation are so inconvenient as to offer a great advantage to the aeroplane, is the line connecting London and Paris. The traveler who has once been through that journey by ordinary means, with its two changes of vehicle, with a channel crossinig which seems to try to live up to the worst things that have ever been said of any sea voyage, and with its multiple examination of baggage, will be anxious to use air transport or

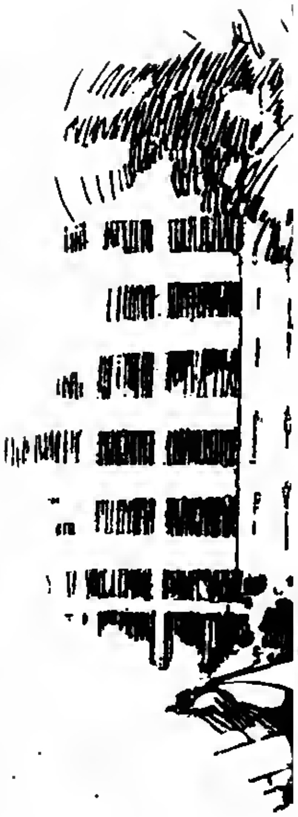
SELLING PROGRAM

In checking over the accompanying program of sales, note that the designation "Q.M. SUPPLIES" is a cloak to a list of 65,000 commodities. Not all of this great number is included in each sale, of course. Nor will the manufacturer and dealer in the aero field be interested in all of the 65,000 items. Your individual needs govern your purchases. Catalogs of each sale will guide you to wise buying.

Sales listed as "AIR SERVICE SUPPLIES" will present some or all of the following commodities:—

Planes and parts; motors and parts; linen and cotton fabrics; scrap steel, iron, bronze, aluminum and brass; helmets, goggles, flying suits and leather coats; oils and lubricants; cameras, kodaks, lenses, chemicals, compasses, stop-watches, clocks, propellers, welding outfits, etc.

SEND FOR CATALOG



By Negotiation

During July and August, at Chicago, Ill., the War Department is conducting one of the greatest sales of machine tools it has ever held. A great variety, and large quantities of machines are offered. Send for full information to Chairman, Chicago District Ordnance Salvage Board, 7400 South Ashland Ave., Chicago, Ill.

The Government reserves the right to reject any or all bids

Better Business

Your hand can dam the mighty Mississippi at its source. Lift your hand, and the labors of a nation cannot halt the majestic sweep of the waters near their mouth.

Business is like the Mississippi. Remove the barrier at the source of supply, and the stream of trade will grow in volume as the rivulet becomes the river.

The War Department today is the greatest single source of supply the business world has ever known. Impounded in its warehouses are millions of dollars worth of materials—bought to meet the acid test of use by your Army in the struggle "over there." Their nature is as varied as the demands of diversified industry.

Better business depends in large measure upon unhindered distribution of this surplus in the channels of trade. Do your part in releasing these stores. The catalogs of offerings show the way. Write:

Chief, Sales Promotion Section, Office, Director of Sales,

Room 2515, Munitions Bldg., Washington, D. C.

ARTMENT

anything else which enables him to avoid those manifold inconveniences in future. A considerable part of the London-Paris passenger traffic is made up of people who travel by air for greater comfort and convenience than they can obtain by land and sea, and some part at least of the express business comes from shippers of fragile or perishable articles desiring to avoid the heavy handling whicb those are likely to receive by transshipment at the channel and during customs examination. Millinery, eggs and flowers have been among the articles frequently shipped by air between the two capitals. In general, the same considerations that make the London-Paris route supremely excellent for exploitation by air will apply to any journey combining land and water transport, or crossing deserts or mountains, where the volume of traffic is not large enough to justify the great expense of good railroad construction. There would be a distinct field for aeronautics from this source in some of our western states and in the Great Lakes district.

In the Texas Oil Fields

Obviously, the second requirement for an air route is that the traffic must exist, and it must be a relatively wealthy traffic willing to pay for high-speed transport. The quantity need not be large, but the economic quality must be high. These conditions are, of course, most readily satisfied between great cities, where, however, there is likely already to be excellent train service between cities and summer resorts at a considerable distance and patronized primarily by the wealthy, and in recently opened districts of great mineral wealth. There have probably been more privately owned aeroplanes employed in connection with the oil industry in the recently developed Texas fields than in any other one way in this country. Speed in locating and developing a source of mineral wealth and taking advantage of the opportunities which appear is all important.

Another requirement, and the last of the very important ones, is that the route must be such that flying will be safe. It is not safe to cross large bodies of water with a land aeroplane. It is not safe to pilot an aeroplane over extensive swamps or forests or deserts or over any other country where the danger of wrecking the aeroplane in a forced landing would maroon the passengers far from the haunts of men. This requirement of good and safe landing places is, unfortunately, often in conflict with the first requirement of a country in which railroads do not operate effectively, and they can only be reconciled by the provision and upkeep of numerous landing places in the undeveloped regions. Tbe British Government has done tbis, for example, in laying out the route from Cairo to Cape Town, with cleared landing fields at reasonably short intervals, most of them offering an opportunity for the obtaining of supplies of various sorts and some being fully equipped airdromes with mechanical assistance available if needed.

Need of Landing Fields

Air transport cannot develop to a high degree, even in the United States, until some steps are taken to provide fields along the route for use in case of emergency. Furthermore, there must be landing fields near the cities. At the present time it takes one and three-quarter hours to fly from the Boston airdrome in Framingham to the New York airdrome in Mineola. To go from Boston to Framingham consumes an hour, and 45 minutes more is lost in getting from Mineola to New York City. The total time, therefore, is just double what is would be if flying fields were available close to each city, and any city which has a piece of undeveloped land in a position where a flying field can be established within a few minutes' ride of the business district should declare itself thrice blessed and seize the golden opportunity without further delay. In the light of two and one-half years' experience in commercial operation of aeroplanes between London and Paris, it is hard to place an estimate on the value that a landing field close to the center of London would have or to guess the increase in traffic which would result from the elimination of the tedious automobile journeys from London out to Crydon and from Le Bourget into Paris.

NAVAL and MILITARY AERONAUTICS

Dedication of Shoen Field

Under the auspices of the 464th Pursuit Squadron, Organized Reserves, the 100-acre tract used as a flying field at Fort Benjamin Harrison, Ind., was dedicated to the memory of Lieut. Carl Schoen on Sunday, May 7th. Lieut. Shoen was an Indianapolis boy, and at the time he was shot down in 1918 he had been credited with seven enemy airplanes. In his last combat he was engaged with a superior number of the enemy. Mrs. Schoen, his mother, was present at the ceremony.

All roads and available space around the field were jammed with the parked cars of the spectators. The crowd surrounded a flag-draped Martin Bomber Transport. The nose of this ship was used as a speaker's platform. Major-General George W. Read, Fifth Corps Area Commander, made an appropriate talk and then introduced Judge Robinson, of Indianapolis, who recounted the life and deeds of Lieut. Shoen and the debt Americans owe to him and his comrades who, through their supreme sacrifice, have shown the way to one hundred per cent Americanism.

Immediately following the program of speeches, there was a battalion parade by the 11th Infantry troops and band stationed at Fort Benjamin Harrison. They passed in review before General Read, Judge Robinson, Mayor Lew Shank and officials of Indianapolis, and the members of the 464th Squadron, who were in uniform.

The spectators were then taken in hand by the Reserve Officers and shown the different planes. The DeHavilands and Curtiss offerings received scant attention because the big Martin "U. S. Transport" began to warm up for the return flight to McCook Field, piloted by its skipper, Lieut. Wade. The day was perfect for flying. Under the leadership of Major Maxwell Kirby, four ships were warmed up, and all members of the Reserve Squadron were given rides. Later on several of them were allowed to solo. For about two hours the field resembled a hive of huge bumble bees, planes alighting and departing, circling and soaring, while they were followed with interest and apprehension from the ground.

Due to the efforts of Major Kirby and a Committee of Reserves, all planes went through with well-oiled smoothness. There was no suggestion of a mishap in flying. The day was a great success from every standpoint. The people were acquainted with the fact that there will be flying in this vicinity, and it will become popular. The Reserves gained worlds of publicity and the 464th Squadron will receive applicants. At least, the organization will become widely known by its efforts.

Air Service Appointments

Brereton, Maj. L. H., from Paris to Washington, D. C., temp. duty, then to Post Field, Ft. Sill.

Wash, Maj. C. W., as Asst. Mil. Attache Paris.

Crissy Field Flying Circus

The Flying Circus for the benefit of the Army Relief Fund was held at Crissy Field on Sunday, May 21st, and was enjoyed by approximately ten thousand visitors. Mather Field was present full strength, bringing some twelve ships to add to the already long line. The events were run off in the following order:—

Battle Formations from Mather Field. 15 DH-4B Battle Planes.

Exhibition of death defying acrobatics and wingwalking, introducing the famous "Breakaway" by Wesley May, "The Supreme Dare-Devil of the Air," on plane piloted by Captain Lowell Yerex, the distinguished English "Ace."

Stunt Flying: Captain Lowell H. Smith, "Fokker" and Lieuts. L. F. Post and John W. Benton, "S. E. 5"; and Sergeant Thomas J. Fowler, "Curtiss JN4-H."

Daring exhibition of Flying Upside-down by Pilot Clyde Pangborn.

Twenty-five Mile Crissy Field Trophy Race between Lieuts. Russell L. Maughan, Geo. A. McHenry, Wm. R. Seeley and Lt. M. S. Boggs, 316th Reserve Squadron.

Changing from Plane to Plane in Mid Air, Wesley May transferring from the upper wing tip of an aeroplane flown by Clyde E. Pangborn to the dangling rope ladder suspended from the aeroplane flown above by Captain Lowell Yerex.

Aerial Combat: Captain L. H. Smith in the "Fokker" and Lieut. John W. Benton in the "S. E. 5."

Exhibition of aerial gunnery, demonstrating a gunnery target towed by an aeroplane, machine guns and bomb dropping. Sergeant Paul D. Andert on the tow target; Lieut. Leo F. Post, Pilot, and Corporal Melvin C. Wignall, Observer, on the attacking aeroplane.

Five-thousand foot dash through space with a parachute, introducing the "Bullet-drop" by Wesley May from a plane piloted by Captain Lowell Yerex.

Grand Aerial Ensemble. Fifty planes of seven different types flying over Crissy Field at one time.

Personal Paragraph

Lieutenants Robert E. Selff and Wm. C. Goldsborough have completed their seven-thousand mile photographic mission, having photographed all available landing fields in Northern California and Nevada.

Mather Field Notes

The members of the 28th Squadron (Bomb.), participated with the City of Sacramento in the observation of Memorial Day on the 30th. Patriotic exercises were held in the cemeteries during the morning and a huge number of city, state and federal organizations paraded at 1.30 P.M., in the afternoon, Lieutenant S. C. Carter commanding the Mather Field contingent.

Civilian fliers at the Field during the week were Mr. L. Morris, with mechanic, en route from Crissy Field to Reno, Nevada; and Mr. Robert Tanner (a former member of his command) in a J.N.4-D, on his way from Gridley to San Francisco, with Mr. M. Delarno as observer.

On behalf of the farm owners adjacent to Mather Field a very active campaign against gophers and squirrels is being waged here under the direction of Mr. W. Jackson of Sacramento, in charge of rodent control for this part of the state. Regardless of all precautions taken by farmers to rid their property of Rodentia, the butt of the target range on the Field made a safe haven for the animals after they had raided the nearby wheatfields, and a corps of workers from Sacramento are getting rid of the pests very quickly.

Buffalo is still producing planes. A train load of Army Training Planes leaving the factory of G. Elias & Bro.

FOREIGN NEWS

The Klémperer Wing Load Indicator

The instrument shown in the attached illustration is one developed by Herr Klemperer, the designer of the well-known Aachen gliders. It is a compact form of indicating accelerometer and gives directly in multiples of gravity the intensity of the foeces on a mass carried by an aeroplane—or other vehicle—due to acceleration.

It therefore serves to indicate the intensity of loading on the wings of an aeroplane produced by manœuvres, or atmospheric disturbances. The indications are in plain figures, 1 corresponding to steady flight and the normal loading due to the weight of the machine, 2 to twice that loading, and so on.

The scale rotates past a fixed pointer, and only a small portion of the scale is visible. Part of the scale—that corresponding to dangerous loads—is coloured red, and the appearance of red through the aperture gives the pilot warning that the particular manœuvre causing that appearance is one subjecting the machine to loads approaching a danger point. Obviously this red portion of the scale can be arranged at any suitable part of the scale to suit machines of varying degrees of strength.

There is nothing novel about this use of an accelerometer, but hitherto this type of instrument has been used only in a form suitable for research work. A clear indicating instrument of this type may be of some value for routine test and demonstration work.

The Coupe Deutsch

It is now announced that the second annual contest for the Coupe Deutsch will take place at Etampes on Sept. 22nd. As regards entries, it is a little early to make any definite statements, but there is certainly little activity in certain camps that are known to regard aeroplane racing favorably.

In France a Nieuport entry is regarded as certain, and it is said that the "Sesquiplane" is being altered accordingly. The plane surface is being reduced by roughly two square metres, and the power is being increased, but whether by "boosting" or a different power unit is not yet known.

A Hanriot entry is contemplated, but it is not known whether the D.H.22 which was designed for last year's contest, and so far has not flown, or a machine at present being designed, will be used.

It is rumored that M. Béchereau, well known as the designer of the Deperdussin monoplanes and the earlier Spads, has under construction at the Letord factory, a high-powered fighting Scout. Also, the Etablissements Bernard are constructing a high-speed all-metal machine, both presumably for the Aviation Militaire, but there is no reason why either or both should not form the basis for entries from both these firms.

It will be remembered that the Borel racer entered for the last Gordon-Bennett contest was merely their very efficient two-seater fighter fitted with racing wings and embodying some minor refinements as to streamlining, etc. This machine, although it did not compete, showed itself, in flight, to be as fast, if not faster, than the winning machine.

The United States have showed themselves to be highly interested in international speed contests, and a resolution signed by Rear-Admiral Moffatt and Major-Gen. Pattrick, the respective chiefs of the U. S. Navy and Army Air Services, was submitted recently to Congress urging official participation in all contests at home and abroad. Also the Aero Club of America have definitely fixed August 15th or thereabouts as the date for elimination trials to be held, if necessary, at Mitchell Field, L. I., should any entries materialize.

At least one entry from Italy is expected, and with the number of Italian competitions that are arranged for this year it is hoped other firms will think it worth while to construct special machines, the qualities of which may warrant their entry for what is generally considered to be the "Blue Riband" of the speed world.

French Aviators Cool to Santos-Dumont

The cool reception which marked the arrival in France of Alberto Santos-Dumont, pioneer builder of dirigible ballons, reached its climax when Rene Fonk, French aviation ace and a Deputy from the Vosges, failed to put in his appearance at the Tuileries, from which he had been advertised to fly in a French balloon with the South American. Fonk left for the Vosges without giving the Aero Club of France any intimation of his decision not to participate in the race.

Although the club officials profess to believe that Fonk was delayed in the Vosges on account of provincial elections, those who are close to him insist that his absence was due to antipathy to the man who at the beginning of the war after collaborating with French aviators manifested a Germanophile attitude and left France to remain in Brazil, his native country, in seclusion while his former colleagues risked their lives.

French Planes Carry Ten Thousand in Year

French commercial airplanes last year covered a distance of more than sixty times the girth of the earth, with only one accident for every 800 trips. In forty accidents, including forced landings with motor trouble, there were only eleven deaths and six persons injured—according to aviation officials, a record not yet achieved by any other country.

The French now have eight lines operating reaching London, Brussels, Rotterdam, Amsterdam, Strasbourg, Prague, Warsaw, Toulouse, Casablanca, Barcelona, Lausanne, Bordeaux, the Riviera and Corsica. The number of passengers carried totaled just over 10,000, with 175,000 tons of baggage and mail carried. There are now 236 machines available, with a combined horsepower of 80,000, and 100 pilots. Schedules are being maintained with 97 per cent efficiency.

London-Paris Express Planes Now More Luxurious Than Ever

The airways are steadily developing smoother and more luxurious travel as the railways did, but at a much faster rate. The latest thing in the Paris service is the new type of Handley-Page saloon express, two of which went off from Croydon recently after being christened by Gen. Brancker as his first performance as Director of Civil Aviation.

Instead of smashing the bottle of champagne against the fragile side of the aeroplane, Gen. Brancker knocked the neck off the bottle with a hammer and splashed the froth against a strip of paper which concealed the names "Princess Mary" and "Prince George."

The new machines carry twelve people—four more than is usual at present—and 500 pounds of baggage. They weigh five and a half tons when fully loaded and have an average cruising speed of ninety miles.

The passengers can move about inside and each one has his own window, which can be opened. The machines are fitted with the wireless telephone and travellers can telephone to London on the way by handing their messages to the pilot. The accommodation generally is that of a first-class railway carriage, with racks for light luggage. Six more of the same type are being built.

Fast passenger aeroplanes between Paris and Cherbourg will now run in conjunction with the ocean services. The Cunard Steamship Company has arranged, as from June 1, with the Messageries Aeriennes Francaise for an aeroplane service to connect with the arrival and departure of the express Cunarders calling at the French port.

By using the air service, passengers will save at least five hours in the journey to and from the French capital.

In the case of passengers arriving from New York, on landing at Cherbourg they will join a waiting motor car and proceed to the aerodrome from which place they will fly direct to Paris. Outward bound passengers can arrange for an aerodrome motor car to call for them at their hotel. Passengers can take a certain amount of baggage.

British Wireless Service

The British Air Ministry announces:—

On and after 15th June, 1922, the forecasts of the meteorological changes anticipated in S. E. England which are included in the aerial route weather reports issued by Wireless Telegraphy from the Air Ministry at 08.35 G. M. T., 11.35 G. M. T. and 14.35 G. M. T. will, for brevity, be issued in code and not in plain language as hitherto. Details of the code are to be found in "Forecast Code for the Abbreviation of Weather Forecasts transmitted by Telegraphy or Radiotelegraphy" (M. O. 244) which may be obtained from H. M. Stationery Office, price 1s. 0d. net.

Great Display at Hendon on June 24th

The Royal Air Force Pageant is again being held for the third year in succession, at the London Aerodrome, Hendon, by kind permission of the Graham White Company, on Saturday, June 24th.

The Pageant is an integral and important part of the annual training of the Royal Air Force and fulfils the same functions as does the Royal Tournament in the case of the Army and Navy, as it is impossible for the Royal Air Force to give any effective display of its work in an enclosed space.

The Pageant provides an opportunity, which it would be difficult to obtain in any other way, of bringing together representatives of the different types of squadrons which carry out the varied work of the Royal Air Force, such as aerial fighting, bombing, reconnaissance and the like, and giving them practice in association with one another. This enhances its value from the training point of view, while a valuable stimulus to keenness and efficiency is provided by the inter-unit competitions and displays.

The experience of the two pageants already held at Hendon has proved that the general public is keenly interested in Service aviation and welcomes the opportunity of obtaining a first hand knowledge of the work of the Royal Air Force.

A programme has been arranged which will fully equal that submitted in previous years. New features are being introduced which will enable the public to appreciate the developments that are constantly taking place in the aerial arm.

Full details of the programme, the most spectacular item of which is the destruction of the desert stronghold by bombing aircraft, will be issued shortly.

ELEMENTARY AERONAUTICS *and* MODEL NOTES

Model Aeroplane Details

(Continued from last week)

Tracter Wing Incidence

Constructing incidence in tractor wings is not met with favor by some flyers but it has several advantages not so apparent at first. On thing is that both wing clips are alike, another, a change of incidence lends stability to a wing and finally it raises the center of pressure (without a surplus of dihedral) to where it belongs in a hollow spar model. It is claimed that not much efficiency is lost by the drop down.

Propeller Shafts

Propellor shafts are very similar to "s" hooks on the rubber end and are generally made of the same size wire. "A" is one with a safety hook attachment. The safety hook bere must be able to pass through the bearing. "B" is part of a plain shaft like the "s" hook "B" on one end. "B" shows how the wire is bent over and back and then pushed through the propeller. In case the propeller is Balsa, and even if it is not it is wise to secure the shaft in place with a little AMBROID cement at "D" and also at "E". At "E" the propeller can be further protected from wear by a thin piece of copper with a hole in it. Three or four washers should be used on each shaft.

Propeller Clutch

The clutch enables the model to make a better glide by allowing the propeller to spin freely after the rubber is unwound. "A" shows motor-base with propeller shaft "B" in place for flight. On "B" washer "C" is brazed or soldered securely in place. The propeller "E" is free to revolve on shaft "B" with two bearings—one on either side "D", until the "F" end of the hook is caught under hook "G" which is fast to propeller "E" by inserting it in the wood and glueing it in the wood with Ambroid. When the rubber is wound up in the proper direction the end of the shaft "B" which is bent over at right angles "F" should be tight against "G" hook on the propeller, thus driving it around when it is released. When the rubber is unwound the propeller should release itself and continue to revolve in the same direction as long as the model continues to glide—thus cutting down the resistance.

Tracter Wing-Clips

Wing clips for tractors are what bold the wing in place and take up the torque of the air-screw, as well as give the wing its incidence in the majority of cases. "A" is the plain style used on Mr. Pond's indoor and outdoor tractors with much success. They are mounted with Ambroid cement only (which accounts for the success). "B" is made of two pieces of flattened wire bound in place with thread. This was the style used by Mr. P. Breckenridge when he broke three tractor records in one day. "C" is a good common style and if a bit of room is left for adjustment up and down, it is a very handy clip. It takes the torque of the propeller well. "C" is for the rear of the wing and "D" is the same thing for the front of the wing. "E" is practically the same thing as "C" and "D" except that it is bent around the motor-base as shown. "E" was used on Mr. Pond's 170 sec. indoor tractor model.

Dope: for Rubber, Covering Surfaces, Etc.

The doping of the wings of a model causes considerable trouble for some constructors, and for others they do not. To this latter class belong those who do not dope their wings at all except the Hydro wings. Dope is only to lay down the "fuzz" of the paper and make it tight and smooth. Dope must be used with considerable good judgment or it will shrink the paper too much and spoil the wing. Acetone with 5 or 10% of banana oil makes a very good dope. Pure banana oil is a good Hydro dope but shrinks most wings out of shape. If shellac is added it will not shrink as much but weighs considerable more. A good way to waterproof the paper without warping the wing in the least is to paint a sheet with banana oil, dip it in water and let it dry before it is put on the wing frame. In this case no more dope is added. For pontoons, three or four coats of banana oil will keep the water out. The under side can also be varnished to good advantage. Test for leaks by dipping in water. The holes cna be plugged with Ambroid. Do not use LePages glue on Hydro machines as it is very likely to loosen up and the parts separate. It is not necessary to dope the wings of light land models. For sticking paper to wings either glue, banana oil, or a mixture of the two can be used with the preference to the second. Ambroid is a very handy glue to use on models as it dries fairly quickly and needs no binding. Anything to be fastened with *Ambroid* should be so arranged that it will not be disturbed until the glue has dried. It is dry when it is amber hrown.

Rib Attachments

In rib attachment A, the front beam is below the rib and the rear beam is above the rib. In B, both beams are below the rib. One turn of thread is sufficient if glued with Le Page's, but Ambroid properly applied will hold without binding. In C, Mr. Hittle has struck terror into the heart of the poor bamboo benders by winding the rib around the wing-beam and tying a knot in itself. At D, the wing-beam is slipped into the split rib and glued into place. In E, the rib is inserted into the beam as shown in two views. If care is used in gluing a butt joint may be made with the use of Ambroid.

Front View of Elevators

Elevator A has a variable incidence along its whole length, and being inefficient is not found on record machines now, but some of the old record machines were equipped in this manner. B, is about the best compromise devised so far to eliminate blocks or supports. C, is a much harder way of doing the same thing as in B. D, is a very efficient elevator, the most efficient in fact, but it takes all the trouble of a wire clip in front to hold it up. Style B, was used on Mr. Pond's record machines and therefore must be of efficient design.

(To be concluded)

RADIO DIGEST

Variometer Is Useful Part in Receiver

One of the most useful instruments in the radio receiving set is the variometer. It is most efficient on a short-wave set, and as the broadcasting stations are all operating, by government decree, upon 360 meters, the variometer finds a very large sphere of usefulness in the radiophone system. It affords a means of getting continuous variation of the inductance in the radio frequency circuits without the disadvantage of sliding contacts or the multipoint switches that are used in other forms of inductance. It also has the advantage that it can be readily and simply constructed.

Another important point in its favor, when used with the vacuum tube sets, is the fact that its peculiar nature permits the variation of its inductance without any break in the continuity of the circuit. This is very important in vacuum tube work, because with the multipoint switches used in other inductances, unless they are very carefully designed and constructed, the circuit is apt to be broken while the adjustments are being made, and in some cases this will tend to paralyze the vacuum tube.

Consists of Stator and Rotor

A variometer is constructed in two sections—one known as the stator and the other as a rotor. The stator, as its name implies, is a stationary winding in a suitable form, while the rotor is a winding upon a coil which rotates upon its axis inside of the stationary winding.

The operation of the variometer is as follows: If the rotor is turned in such manner that its plane coincides with the plane of the stationary coil, the current will circle through both windings in the same direction and their magnetic fields will add to each other. The self-induction of the variometer is then at its maximum point.

Should the rotor be turned completely around, the current will then flow through the two coils in opposite directions and the result will be that the two magnetic fields will oppose each other and the self-induction of the variometer will be at the minimum, or practically zero. Of course, if the rotor coil is at any other angle, we obtain varying degrees of self-induction, and it is by this means that tuning is affected with the variometer.

Variometers Standardized

In the past couple of years the variometers used in receiving circuits have become more or less standardized, and the forms upon which the two windings are laid can be obtained ready-made by the radio fan. They invariably come in three pieces—two of the pieces representing sections of the stator and the third piece being the rotor. The latter is invariably made in ball form.

For the novice who desires to construct his own variometer without obtaining any of these standard parts, the following instructions should be followed: Obtain two cardboard tubes—one six inches in diameter and the other five inches in diameter, both being two inches in length. Upon these wind single layers of No. 24 S. C. C. wire. The winding will not be continuously made, because in the middle of each tube a space of one-quarter inch must be left so that the shaft which revolves the rotor can be passed through both coils. The same amount of wire should be placed on each tube, completely filling the tube with the exception of the one-quarter-inch space in the middle and a slight space on each edge.

The outer tube can be mounted on a wooden frame after a hole has been drilled sufficiently large enough to take the piece of quarter-inch round brass rod eight inches in length. The inner tube should be fastened to this brass rod so that it will revolve with it. One end of the rod will have an adjusting knob attached to it. A scale can be added if desired. The turns should be thoroughly shellacked after the winding is complete, in order to prevent that from loosening up.

Standard Blocks Can Be Used

With the standard wooden blocks or composition blocks that are sold for variometer purposes all that will be necessary is to wind the spaces left for winding with No. 22 D. C. C. wire, so that the entire space is filled up. At the first glance it will look as though the task of wiring the stator section will be extremely difficult, but if these instructions are followed it will not be a very hard task.

Cover the sections of the stator with a coat of shellac and before this dries put your winding upon it, seeing that the winding is snug and tight. After this is completed cover with another coat of shellac and force the windings into position and then allow it to dry.

In assembling the variometer, the end of the stator winding will be carried on and connected to the beginning of the rotor winding. In this case, however, a flexible connection of sufficient length must be left between the two coils in order to permit the rotor to be turned completely around without breaking the connection. Another way is to use the brass shaft as a means of connecting the two coils together, so that the rotor coil can be spun completely around.

Majestic Radio Among Finest in the World

The arrival of the gigantic White Star liner *Majestic* in New York emphasizes the wonderful and rapid strides that have been made in the development of wireless telegraph apparatus within the past few years. This remarkable progress has recently been overshadowed by the spectacular expansion of the radiophone caused by the sudden public favor, but it has been none the less important.

Within a comparatively small space in the wireless cabin of the world's largest ship there is installed one of the most complete, compact and efficient wireless systems yet devised. The giant ship carries two types of transmitting equipment and two types of receivers. The transmitting apparatus consists of a 1½-kilowatt quench gap spark set and a continuous wave transmitter using one big vacuum tube with an output of 1½ kilowatts. The range of the quench gap set is approximately 400 miles, while that of the continuous wave set is in the neighborhood of 1,000 miles.

The receiving apparatus consists of a complete receiver with a wave length range covering everything now in daily use and a radio-goniometer, or direction finder. The latter is probably the most unique of the radio equipment aboard, and differs materially from the standard American practice in that it utilizes two loop aerials of extremely large dimensions, permanently rigged on the ship, in an unvarying condition.

Spark Used for General Calls

At the first glance it might seem superfluous to install a spark transmitter on a ship when its efficiency as compared with the continuous transmitter is so low. In this conection it must be remembered that continuous waves are extremely sharp in their tuning, while the spark is much broader. Under the circumstances, therefore, the spark is much better suited for the purposes of sending out general calls, and particularly so for sending out the distress call.

In addition to this the two types of transmitting apparatus naturally fall into two well-defined spheres of usefulness aboard. The continuous wave set operates on wave lengths ranging between 2,000 and 2,500 meters, and is well suited for communicating with the long-distance shore stations. The quench gap set is attuned to the standard short wave ranges set aside for ships by the International Radio Convention and is suited for ship-to-ship communication and the ordinary form of ship-to-shore work.

The continuous wave set operates on alternating current, which is rectified by two element rectifiers, of which there are two installed in the C. W. panel. The oscillating tube has an output of 1,500 watts. The transmitting equipment is completed by the addition of a 250-watt auxiliary quench gap set, designed for emergency purposes.

Direction Finder Is Unique

The regular receiving equipment, while very sensitive, does not depart from standard practice. It is in the radio-goniometer, however, that the chief interest in the apparatus aboard the *Majestic* lies. This consists of a special type of receiving transformer, and a six-valve amplifier. The latter has four stages of radio frequency amplification, one detector bulb and one stage of audio frequency amplification—or, as the English call it, a note magnifier.

The remarkable thing about this amplifier set is that all of the six bulbs are controlled by one rheostat and a potentiometer which controls the initial grid potential of all six tubes. The audio frequency section of the amplifier can be switched out of the circuit, if not required. This is arranged when taking bearings on stations that are comparatively close.

As has already been said, the loops used in conjunction with the direction finder are quite novel. They are based on the Bellini-Tosi system, and consist of a thwartship loop and a fore and aft loop, rigged up close to the wireless cabin, and supported in a manner that has now become standard on British ships.

Operator Aids Navigation

With this apparatus the wireless operator becomes an important factor in the navigation of the ship, especially in foggy weather. With his aid the position of the

Digitized by Google

ship can be determined within a very few minutes by taking bearings upon well-known land stations, as all of the latter are listed in the international call books with their exact latitude and longitude. It is also possible to tell the exact bearing of other ships.

In foggy weather it is possible by means of the direction finder to determine roughly the distance of another ship, while its direction can be determined with exactitude. This is an important function, and one bringing a new factor of safety to navigation, as it will tend to reduce collisions at sea during fog.

In addition to this the direction finder has an important use in badly congested wireless areas, such as that in the vicinity of New York Harbor. In these cases, where interference is very bad as a result of so many stations attempting to work simultaneously, the operator can change over to his direction finding apparatus and use it for receiving purposes, thus cutting out all interference except that which emanates from the same direction as the station he desires to listen to.

Condenser Aerial Tested by Bureau of Standards

The Bureau of Standards has been conducting a series of experiments with condenser aerials which show very promising results for short-wave reception. This type of aerial is very useful for mobile work, and was used to some extent during the late war. It consists of two strips of wire netting, composed of copper mesh similar to that used for mosquito screens. One strip suspended parallel to the ground acts as the aerial, and the other strip laid just above the earth acts as a ground. These strips are from 6 to 15 feet long and from 18 to 36 inches wide, and act as two plates of a condenser.

In a report of the experiments so far conducted, J. C. Warner, the assistant physicist of the radio laboratory of the bureau, says:

"Experimental results show that a condenser antenna of small dimensions gives excellent results when used at wave-lengths below 400 meters. At longer wave-lengths it suffers by comparison with the coil antenna when the dimensions are kept small enough for portability.

"It is useless for directional work unless used with a coil antenna, but may be used in places where the sharp directional characteristics of the coil are objectionable. By proper design and by taking precautions to keep dielectric losses low the effective resistance may be reduced to a value lower than can be obtained either with the coil antenna or the ordinary elevated antenna.

"On account of this low resistance and ease of construction this form of antenna should be of great value in portable short-wave radio stations, such as are used for military purposes and on aeroplanes, although in the latter case some difficulty may be experienced in keeping down dielecric losses.

"It is evident that the study of this interesting form of antenna is by no means complete. Its use as a transmitting antenna offers a wide field for investigation, and a large amount of work remains to be done in following up the investigations, which have only been started in this study. For example, signal intensity measurements should be made with a calibrated detector set or with a radio-frequency comparison method, so that the actual current or E. M. F. in the antenna is measured. Further work should be done in determining the best design of antenna for a given wave-length and for minimum resistance. Also, this antenna furnishes a means of studying the form of the electro-magnetic wave, and a large amount of work might be spent profitably in this study, as well as in the checking of transmission formulas."

Radio Ameliorates Hard Tasks of Men On Isolated Duty

Improved service for shipping and better living conditions for members of the United States Lighthouse Service have resulted from the use of the radio, according to the Department of Commerce.

Formerly a tender would be dispatched from a lighthouse depot to repair or replace a buoy. After a round trip of perhaps several hundred miles it would often be necessary to repeat the journey to take care of another buoy in the same general locality. The radio is eliminating this waste of time, money and material as the vessels can now be kept informed as to when and where they are to be located. This enables them to complete the work in any particular locality before proceeding to another.

Last month the Department of Commerce authorized small additions to the radio equipment of several of its larger sea-going tenders to enable the crews to receive the radio broadcasting services for instruction and entertainment purposes, and consideration is now being given to making some similar use of the radio equipment placed on many of the lightships during the war, but not used since the Armistice, as well as on the principal outside lightships where a regular radio service is now maintained These latter, such as Nantucket and Diamond Shoals lightships, are the outpost radio stations on our coasts, reporting incoming ships, forwarding messages, and sending word of vessels in distress.

With the co-operation of the Navy, radio telephones have recently been installed at several of the remote lighthouses in Alaska.

Some of the lightships are also equipped as radio fog-signal stations, with the new Department of Commerce system, this being used during foggy weather to furnish accurate bearings to ships possessing the radio compass.

According to George R. Putnam, Commissioner of Lighthouses, radio should be a great boon in relieving the lonely and monotonous life of the faithful keepers at isolated stations both on lightships and at lighthouses. The keepers at the Alaska lighthouses at the entrance to Bering Sea remain at their posts for three years on a stretch; they have been without mail for ten months. At Tillamook Rock Light, off the Pacific Coast, bad weather has prevented direct communication with the shore for periods of seven weeks at a time. On the offshore lightships supplies are received only once a month, and the tenders often work in remote localities. Relaxation at these stations depends chiefly upon libraries furnished by the Government and donated magazines with an occasional phonograph presented through a thoughtful friend.

Developing Phones for Motor Cars

One of the latest radio developments is the radio car. A leading motor company has proved that radio equipment operates satisfactorily in an automobile without the use of a "ground."

The possibilities which this portable radio receiving station offers include an almost limitless field.

With a car equipped in the fashion depicted it is possible for a family to drive anywhere within 100 miles or so of a broadcasting station and picnic while the radio in their car amuses or instructs them. Education and entertainment can be made transportable. With a few cars equipped as this one, a clergyman could talk to a dozen congregations at once. Similarly, if the United States Department of Agriculture had similar radio equipment in the hands of its county agents, department experts could talk to thousands of farmers at once and thus bring the tremendous added benefits to agricultural districts that would otherwise be impossible.

Likewise the political candidate could send a radio equipped car to every voting area in his State and talk to all of his constituents at the same time, thus saving his vocal chords and making it possible for his hearers to stop listening when they were tired.

The installation of this equipment is so simple that it is possible to adapt it to many uses. It is only a matter of a few moments to remove the radio equipment from the car when it is not desired. It can then be used in the home or the office or any other desired place.

Just as anywhere on the high seas ships can keep constantly in touch with ports and other ships through the use of the radio, now the automobile—the land ship—can immensely facilitate distribution of information to the great benefit of mankind.

One ingenious amateur, by utilizing the power of the generator on his car, not only receives messages, but also transmits them.

Such equipment makes possible the use of motor cars as scouts or reporters of crops, weather or news messages from any part of the country.

The news reporter need no longer be obliged to beat his rivals to the wire. With a car equipped to talk instantly and directly with the radio office of his paper, he is free from all restrictions or competition.

Finds Manicure File Handy in Radio Kit

Dr. A. R. Curttis, of Rutherford, N. J., has added a manicure file to the necessary tools in his radio kit. To quote the doctor:

"In working around my crystal detector the other day listening in the sound was not clear, and somehow my fingers seemed too clumsy to get the detector at the identical point where it would be clearest. I happened to pick up a thin manicure file and slightly tapped the detector arm and just touched the galena with the whisker and got a most beautiful clear sound, and since then I have used this method, namely, tapping slightly with the file up or down with splendid results."

Vacuum Tube as Amplifier and Detector

The genesis of the vacuum tube, which is such an important factor in radio receiving apparatus, was described in an article in this section last week. In this story it is my intention to describe just how the wonderful instrument acts as a detector and amplifier. By doing so it might be well to point out one of the unusual possibilities of this instrument that is now engaging the attention of scientists.

Recently I was at a demonstration of one of these tubes producing alternating current of any desired frequency with a total outnut of 10 kilowatts of power. This means that in the very near future the vacuum tube will entirely discard the bulky and cumbersome machinery now used for the production of alternating current.

Feed-back System Discovered

In the last article I described the development of the vacuum tube from the

Learn *to* Fly

Aviation is making such strides that it needs more men right now

You Can Learn To Fly

I can teach you how to become a successful pilot in a short time. My course is so arranged that you get only the things you need to make you a good aviator.

The Diggins Extension Course

is up-to-date, teaches you what you must know to become an expert flyer. This course is written by competent instructors right on my flying field. It is kept right up to the minute—all new developments in aviation are included. That is why it is recognised as the most complete and practical course offered today. My course saves you time and money because it prepares you at home so that you are ready to begin flying the day you arrive at the flying school.

Superior Points of the Diggins School

1. The Diggins school is the oldest, largest and most complete commercial aviation school in America.
2. The Diggins school is located in Chicago, the center of Aviation.
3. Living quarters and free employment service are maintained for students.
4. Diggins guarantees to make you a pilot.
5. Diggins' pilots get top notch salaries.
6. References, any aero club in America.

WRITE TODAY Write today for the new Diggins beautifully illustrated catalog.

The Ralph C. Diggins School of Aeronautics

Dept. 8 140 N. Dearborn St. Chicago, Ill.

(*Concluded from page* 355)

time that Edison first observed the effect of its practical application by Professor Fleming; and finally, the addition of the grid by Dr. Lee deForest. Up to this time we had a vacuum tube, but its possibilities were really unknown until Edwin H. Armstrong, a young American amateur, discovered the feed-back principles of transforming it from a simple vacuum tube into an electrical oscillator—a discovery which has given to it all of its remarkable possibilities and made it really and truly the modern Aladdin's lamp.

Now the manner in which the vacuum tube functions as a detector is as follows: As soon as the filament is lighted a train of electrons is thrown off from the filament and these bombard the plate. They are in reality particles of negatively charged matter, which actually bombard the plate with terrific impact. They afford a path for negative electricity to pass between the filament and the plate, and in order to assist the passage of this electricity the plate is charged with a positive potential. The grid enables us to control the action of the tube for this purpose.

When the incoming electro-magnetic waves pass over the aerial a very high frequency alternating current is induced in the oscillating circuit connected with the aerial, which passes this current on to the vacuum tube. The vacuum tube will only allow the negative half of this alternating current to pass through it. It completely checks the positive half and therefore acts as an electric valve in exactly the same way as the ordinary valve operates in a water-pipe system.

Pulsating Current Works Phone

We have, therefore, on the other side of the vacuum tube a current of electricity that is a pulsating current flowing in one direction only, and the telephone receiver is now able to respond to it. That is the manner in which the tube acts as a detector. As an amplifier, a slightly different condition exists and a different action takes place. In this case we have what is known as a "trigger effect," and the action of the tube in amplifying can be best described by using the trigger effect as an analogy.

If you study the mechanism of a rifle you will realize that when you cock the gun you have to use a great deal of force to pull the hammer back against the spring in the gun. When you pull the hammer back, what you actually do is to store up a certain amount of energy in the spring of the gun, which lies dormant until such time as you bring it into play by pulling the trigger. A little thought will show you how minute the pressure is that you exert on the trigger itself when firing the gun, but by releasing the trigger you bring into play the larger amount of energy that is stored up in the spring, and this forces the hammer against the cartridge in the gun with such force that the cartridge is exploded. This is exactly what the vacuum tube does—it controls the larger amount of energy that is stored up in the battery connected to the plate on the vacuum tube.. When the weak, incoming current reaches the grid or "control element" of the tube it releases this stored-up energy by pulling the grid trigger and permitting the plate current to come into play in the circuit. This action, of course, can be duplicated in successive stages of amplification.

Regeneration Described

It is this action that is also brought into play in the regenerative circuit. The tube, having acted as a detector, then passes its slightly increased current through the inductance in the plate circuit, and this inductance, being inductively coupled to the oscillating circuit, induces a still stronger current in that oscillating circuit, which again passes through the vacuum tube, releasing still greater energy in the plate circuit, and this action passes around again performing the same function, always simultaneously, until the certain maximum condition is reached.

This regenerative action can best be explained by using the analogy of the ordinary telephone. Sometimes, when the telephone rings and you lift off the hook and central still continues ringing, you occasionally get peeved and place the receiver to the mouthpiece of your telephone. The result is that gradually and rapidly you get a tremendous buzzing effect that finally reaches a loud and terrific whistle. What has taken place is simply this: The sound vibrations received in the telephone receiver have been fed back into the mouthpiece of the transmitter and the transmitter, of course, increases the sound and passes it around the circuit again to the receiver, which then again transfers it to the transmitter of the mouthpiece until the maximum, final strength is attained, which results in the terrible whistling, howling sounds that appear in the telephone.

GOODYEAR IS READY TO HELP

Copyright 1922, by The Goodyear Tire & Rubber Co., Inc.

As larger and more powerful ships take to the air, Goodyear's alliance with aviation is strengthened. For an experience as old as the airplane itself enables Goodyear to anticipate and fill the needs of progressive aircraft builders.

For example, Goodyear Airplane Tires are now available in sizes up to 44 x 10 inches, the largest being designed to care for a load of 6,000 pounds per wheel. And doubtless there will be bigger Goodyear Airplane Tires in the near future.

Goodyear's steady effort to assist the advancement of flying is not limited to the development of Airplane Tires, or other essential equipment for heavier-than-air machines.

For no mention of the progress accomplished in balloon or dirigible work can be made without thought of Goodyear's aid and firmly established position in this important branch of aeronautics.

America's Finest Commercial Aeroplane

Built to carry three people comfortably, the C-6 Oriole with a full load takes off and lands in a remarkably small space.

Its compactness, beauty, strength, and comfort make it the finest ship for the sportsman to fly. With an electric starter, door for easy entrance, luggage compartment, large roomy cockpits, pleasing lines and color, there is little to be desired.

For the commercial operator, the Oriole is ideal. Its economical, reliable C-6 motor of 160 horsepower gives a pilot that "grand and glorious feeling" which nothing but a wonderful motor can give. Its attractiveness, comfort for passenger and pilot, long cruising range and high ceiling are some of the many features most desired for commercial flying.

For further information, demonstration and prices of this remarkable ship communicate with any Curtiss sales representative or

VOL. XV | NEW YORK, JUNE 26, 1922 | No. 16

IMPORTANT EDITORIAL ANNOUNCEMENT

WITH this issue AERIAL AGE will cease publication as a weekly magazine. It will henceforth appear as a monthly. The first issue in the new form will be dated August 1st, 1922, and will appear on July 18.

This change has been decided on after the most careful consideration of the present aeronautic situation and in an attempt to produce a magazine that will best develop and increase interest in aeronautics on the part of the American people.

The new AERIAL AGE will be greatly increased in size, will be printed on better quality paper, with cover in two colors. It will contain all of the regular departments and features of the present AERIAL AGE, and will have in addition specially written illustrated articles by world authorities, written from the point of view of increasing public interest in aeronautics.

It is contemplated that such a magazine will have a much wider appeal to the American people, and only by such a widespread appeal can we hope to be successful in properly presenting aeronautics to the American public.

THE NEWS OF THE WEEK

Detroit Aerial Carnival

The first aerial carnival and flying meet for Detroit will be held under the auspices of the 310th Aero Squadron, 85th Division, U. S. A., on July 1, 2, 3 and 4. The preliminary announcement concerning the carnival follows:

In the past, Detroit has been sadly lacking in its aviation enthusiasm. One of the most important reasons for holding this meet is that, while Detroit and Wayne County have had assigned to them a Reserve Aerial Squadron, designated as the 310th Observation Squadron, 85th Division, U. S. A., Congress has failed to provide sufficient appropriations necessary to carry on the practical work such as the squadron requires to be accurate. Therefore, to secure the enthusiasm and support, civic and industrial interest of the community, it was felt that some tangible demonstration should be given to attain these ends.

The success of this event will not only enable the squadron to obtain the necessary funds to carry on operations at Selfridge Field, but will arouse interest among public and industrial organizations in this locality in preparation of the coming era of aerial transportation and the benefits of having Detroit on the Aerial Mail Route. The whole object is to promote aviation activity in every sense of the word.

The event will be supported in part by the Detroit Aero Squadron, a pure "dyed-in-the-wool" live organization, composed of between fifty and seventy-five flyers who have served in the American and Canadian Air Forces during the World War; in addition to a large number of observers, combat gunners, air service engineers, balloon men, mechanics and others familiar with the work and possibilities of aviation.

The First Air Carnival and Flying Meet is designed to interest the public from the commercial and industrial point of view, rather than from a sporting standpoint. It is particularly valuable from a viewpoint of National Defense and Preparedness, because our Government does not maintain a completely equipped and operating Air Service in times of peace.

Therefore, only through encouraging and upbuilding a Merchant Air Marine of trained personnel, by those qualified, can the country in general realize the great economic possibilities of Aerial Transportation. These two organizations are foremost in both lines of endeavor; one from the military standpoint, whose training was secured at enormous expense during the war, and others who have had a great deal of experience but are not connected with military organizations. All of this experience and enthusiasm will be given towards making Detroit the hub of aeronautic activities in the United States—which means the development of Commercial Aviation in Detroit and the opening of many possibilities from an industrial standpoint.

Larsen Responds to Rickenbacker

New York—Aroused by what he terms unfair criticism of American aviation, in statements attributed to Capt. E. V. Rickenbacker, whose plane was so badly damaged at Omaha, Neb., that he was forced to abandon his around-the-country flight, John M. Larsen, who improved the all-metal monoplane, issued a statement pointing out that there are many machines which could have made the trip successfully. Rickenbacker is quoted as saying, "no plane in the United States is fitted to make such a tour."

"Capt. Rickenbacker was my guest on a flight across the continent and back," said Mr. Larsen. "We made the trip easily. A pilot, a mechanician, and I flew from Omaha to Philadelphia two years ago without stopping, between daylight and dark. We carried much baggage also. The U. S. Air Service is flying many kinds of machines every day, and the Air Mail flies daily between New York and San Francisco with an efficiency performance of 95%."

Mr. Larsen, who is a Governor of the Aeronautical Chamber of Commerce of America, said that reports received by the Chamber indicate that more than 250,000 civilians flew in aircraft last year, more than 3,000,000 miles. He himself traveled from New York to the Arctic Circle and down into Mexico before returning to Manhattan in the same plane in which he started. He has traveled more than 300,000 miles by air.

"Most of my flying has been done in planes of similar type as that which Rickenbacker attempted to use," said Mr. Larsen. "The machine he used was an obsolete model, two years old, and one of three or four which had been withdrawn by the Post Office Department and sold, for a few hundred dollars, as salvage. They lacked the improvements I have made on the all-metal monoplanes since first introducing them into this country. Personally, I think Capt. Rickenbacker was misquoted or that he made the statement without realizing its full meaning."

The Giant Johan with aviator Horchem and his wife standing under his outstretched arms, in front of the Laird Swallow in which Horchem took Johan for a flight, under wager thnt with the giant in tho cockpit the Swallow would never get off the ground. However, at tho ond of five minutes they had climhed to an altitude of fifteen hundred feet, a most remarkahle feat for a ship tho siso of the Swallow, considering ths load. Johan is 24 ysars old, is 8 feet, 9½ inches tall, wsars a 22½ sixe collar and a numher 20 shoe, weighs 503 pounds

Spokane News

Spokane, Wash.—Interest in aviation in this city has been substantially stimulated as a result of the visit to the city of Rear Admiral W. F. Fullam, U. S. Navy, retired. The admiral is swinging around the circuit of army corps areas as the representative of the National Aeronautical Association. He has a breezy personality of exceeding charm and makes an exceptionally efficient envoy for the organization which planned the tour.

Arriving at Spokane early on the morning of June 5, Admiral Fullam was met at the depot by a delegation of representative citizens, including the mayor of Spokane and president of the Chamber of Commerce. Military Affairs Committee of the Chamber of Commerce is especially charged with the development of aviation in Spokane, and the committee was well represented in the reception committee. Thereafter Admiral Fullam's time was fully occupied. He spoke at the high school auditoriums, addressed the Chamber of Commerce, spoke to the garrison at Fort George Wright and was entertained at luncheons and dinners. The newspapers devoted a large amount of space to his visit with illustrations.

Determination to place the Spokane municipal aviation field at Parkwater in line with the best fields in the Northwest was expressed subsequently in a discussion of aviation by members of the city park board. Commissioner J. C. Argall, who formed part of the air board that attended Rear Admiral Fullam, reported that the admiral was favorably impressed with the Spokane field and promised development of aviation in a commercial way if Spokane got in line with other cities making a strong bid as aviation centers.

Adoption of rules to govern the air was delayed until after action is taken by the National Aeronautical Society at its convention in September, when nation-wide flying rules are to be adopted in conjunction with the army and the navy. Temporary rules will be adopted to govern flyers using the Parkwater municipal field this year. It was voted to make the fee for the season $5 a ship and to have the permit revocable by the park board at any time. All permits are to be issued subject to such rules as the board may adopt.

Personal Par

Arriving on the S.S. Pan America of the Munson Steamship Line from Rio de Janeiro on June 15th was Orton Hoover, Mrs. Hoover and their little daughter.

Mr. Hoover was formerly a Captain in the U. S. Army and is in charge of all aviation at the Brazilian Exposition. He reported having just sold forty-two Curtiss airplanes to the Brazilian Government.

The AIRCRAFT TRADE REVIEW

Automobile and Aircraft Manufacturers Launch Export Campaign

New York.—A united campaign to sell American automotive transportation to the world was begun to-day on the departure from New York of Gordon Lee, Chief of the Automotive Division, Bureau of Foreign and Domestic Commerce, Department of Commerce, who during the next two months will make a nation-wide tour, visiting a score or more cities.

Mr. Lee and Major Horace M. Hickam, representing the Army Air Service, who flew to New York from Washington, addressed a conference of automotive manufacturers at the Transportation Club. The conference was attended by representatives of the National Automobile Chamber of Commerce, Motor and Accessory Manufacturers' Association, Aeronautical Chamber of Commerce, Automotive Equipment Association, Motorcycle and Allied Trades Association, National Association of Engine and Boat Manufacturers, Association of Automotive Equipment Manufacturers, The Class Journal Company, and The Black & Decker Mfg. Co.

The campaign embraces the development of the foreign market for American constructed automobiles, motor trucks, aircraft, motorcycles, and motor boats. Mr. Lee expects to fly between many cities on his trip.

Progress of Aviation Matters in Congress

The following memoranda concerning progress of aviation matters in Congress has been prepared by the Aeronautical Chamber of Commerce:

April 12—*House*

Mr. Sisson discusses the Navy Bill (H. R. 11228). He believes the battleship is dead and has been supplemented by the aeroplane. He believes that the nation that controls the air controls the sea and the nation that controls the sea controls the world.

May 2—*House*

Mr. Oldfield: A bill (H. R. 11515) providing for the purchase of certain inventions, designs, and methods of aircraft, aircraft parts, and aviation technique of Edwin Fairfax Naulty of New York; to the Committee on Appropriations.

May 8—*House*

Conference report of the Post Office Bill (H. R. 9859) submitted. In amendment No. 40, $1,900,000 is provided for air mail service.

May 9—*House*

Brief filed with the Department of Justice by the Contract Audit Section of the Air Service in the Lincoln Motor Case printed in the record.

May 13—*House*

Post Office Bill (H. R. 0859). Appropriation of $1,000,000 for air mail passed House.

May 15—*House*

Discussion of aircraft contracts in the consideration of H. R. 11645 a bill providing appropriations for the prosecution of the war contracts.

May 17—*Senate*

The Vice-President laid before the Senate a communication from the Secretary of War, transmitting in response to S. Res. 266 information relative to a school of aeronautics; which was referred to the Committee of Military Affairs.

House

Mr. Hicks in H. R. 11214, a bill authorizing the President to scrap certain vessels in conformity with the provisions of the Five-Power Naval Treaty, urges the converting of two battle cruisers into aircraft carriers.

May 20—*House*

Mr. Jefferies of Nebraska: a bill (H. R. 11723) to authorize and provide for payment of amounts expended in construction of hangars and maintenance of flying fields for use in the Air Mail Service of the Post Office Department; to the Committee on Post Office and Post Roads.

May 27—*House*

Mr. Hicks unanimous consent to lay on the table H. R. 5219, a bill to create a Bureau of Aeronautics in the Department of the Navy, and the Bill H. R. 6297 authorizing the construction of an aeroplane carrier for the Navy of the United States.

May 31—*Senate*

Vice-President laid before the Senate a communication from the Acting Secretary of the Navy, transmitting in further response to Senate Resolution 266, agreed to April 5, 1922, information relative to the establishment of an academy of aeronautics at the Naval Academy and the manufacturer of aircraft at naval stations, etc., which was referred to the Committee on Naval Affairs and ordered to be printed.

June 2—*Senate*

War Department appropriations (H. R. 10871). Aircraft appropriations amendments agreed to. Amendment allowing $400,000 for Helium experimentation reduced to $300,000 and agreed to.

Aircraft Appropriations

	Allowed in Budget	*House*	*Senate*
Navy Bill—H. R. 11228	$17,043,310	$7,866,950	
Army Bill—H. R. 10871	15,210,770	12,431,000	*$13,000,000
Air Mail—H. R. 9859	2,200,000	1,900,000	1,900,000
Nat'l. Adv. Comm. Aero.—H. R. 9981	250,000	210,000	210,000

* Still under discussion. The helium appropriation has been cut from $400,000 to $300,000.

No appropriation bill has been signed as yet by the President. The Army and Navy bills are being held up in the Senate on account of the tariff bill. The other bills are either in conference committees or the conference reports of these committees are waiting approval of Congress before going to the President.

The Navy Bill was reported by the Senate Committee June 10th, 1922. This Report raised the appropriations for aircraft to $14,703,950.

To Study Plans of JR-1

Washington.—A special committee of leading engineers and structural experts appointed by the National Advisory Committee for Aeronautics met in this city May 18 to make a complete and thorough study of the Navy's giant airship ZR-1, as requested by Rear Admiral William A. Moffett, Chief of Naval Aviation.

The committee is composed of Henry Goldmark, a consulting civil engineer of New York, who was responsible for the design of the great steel lock gates of the Panama Canal; William Hovgaard, professor of naval architecture at the Massachusetts Institute of Technology, Boston; W. Watters Pagon, a consulting civil engineer of Baltimore, and an expert on bridge and structural steel work; Dr. L. B. Tuckerman, engineer-physicist of the Bureau of Standards, who was connected with the tests of the full-sized structural parts of the ZR-1; and Dr. Max Munk, technical assistant of the National Advisory Committee for Aeronautics and an expert on aerodynamics.

At a recent meeting of the National Advisory Committee for Aeronautics, Admiral Moffett, a member of the Advisory Committee, requested that a detailed technical study of the plans for the Navy's first fleet airship, parts of which are now being fabricated, be made by a special committee to check the plans as prepared by naval designers. Accordingly, the Special Committee on Design of Airship ZR-1 was organized by Dr. Joseph S. Ames, chairman of the Executive Committee, and instructed to make a thorough investigation and prepare a report. The object of the report is to pass upon the design and calculations, including the method of determining the load factor and factors of safety used in the design submitted by the Naval Bureau of Aeronautics.

It is estimated that the special committee will require ten to twelve weeks to complete its work and submit report to the National Advisory Committee for Aeronautics.

Seventh Corps Association

The Commercial Aeronautical Association of the Seventh Corps Area has had its Constitution and By-Laws printed in a neat booklet, which will be supplied to anyone interested on applying to Ralph W. Cram, Davenport, Iowa, president, or John B. Coleman, Sioux City, Ia., secretary. The association is organized to promote the interests of aviation, the location of landing fields and to do everything possible for the development of commercial aviation in the eight states comprising the Seventh Corps area. It expects in September to become a district of the proposed National Aeronautical Association to be organized at Detroit.

THEORY OF THE SLOTTED WING*

Lecture by A. BETZ, Göttingen

THROUGH the intensive study of all technical aviation problems during the war, the most important aeroplane parts, especially the wing, were so thoroughly tested as to create the impression that no further substantial improvement was possible. The characteristics of the different wing sections were sufficiently known to enable one to select the most suitable section for almost any purpose.

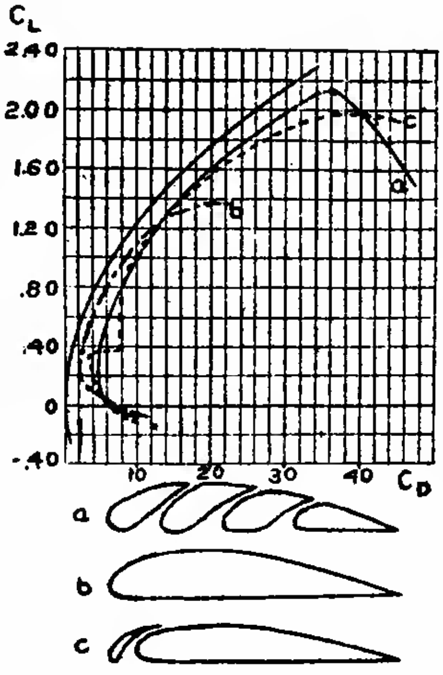
Then the discovery by Lachmann and Handley Page suddenly revealed entirely new possibilities and the wing section again became a rich field of problems. As probably you all know, this discovery consisted in making one or more slots in the wing section (Fig. 1). In this way it is possible to use the wing at higher angles of attack and thus considerably increase the lift. The lift-drag ratio, however, seems to be no better in general than for ordinary wing sections. The advantage lies principally in the ability to vary the coefficient of lift, and hence the speed, within considerably wider limits. Hereby the difficulties of taking off and landing are diminished and greater flight speeds made possible. Our knowledge of the behavior of such slotted wings under the most diverse conditions is, unfortunately, very limited, and there is still much work to do before we shall have carried our investigations so far as to be able to choose, from the many possible modifications, the one best adapted for any given purpose.

The question of the most practical importance is what must be done in order that with an aeroplane we can obtain the best possible lift-drag ratio if the lift-coefficient is low and, in addition, be able to reach by easily made changes, a considerably higher coefficient of lift, where the lift-drag ratio does not need to be especially good. The former condition would be used in ordinary horizontal flight and the latter in taking off or in landing. The purely experimental solution of all the problems connected with these new wing sections is rendered very difficult by the large number of possible modifications. The most diverse cross-sections may be given the component parts of the wing and their relative size may be varied, thus bringing the slot nearer either the leading or trailing edge. Furthermore, the relative position of the parts and the width of the intervening slot may be varied. Lastly, there is the possibility of varying the number of the component wing-parts by the introduction of one or more slots. Although, for structural reasons, many forms do not come into practical consideration, the number of possibilities is still very large.

The experimental work will be considerably simplified and rendered more productive of results, if we succeed in obtaining at least an approximate idea of what takes place. We are still, however, far from being able to give a complete theoretical explanation of the phenomena of slotted wings. Nevertheless, we can contribute something toward the explanation of the unusual increase of the lift coefficient. I do not wish, however, to create the impression that what I am about to say is conclusive. I wish rather to bring the matter up for discussion, in the hope that still other viewpoints may be presented, which will help to clarify the problem.

We must first consider the question as to how it happens that, with a given wing section, the lift coefficient cannot be increased at will. In order to answer this fundamental question, we must consider more carefully the process by which lift is generated. It is known that lift is produced by the greater velocity, and consequently smaller pressure, of the air on the upper side of the wing, than on the lower (Fig. 2.). This difference must vanish at the trailing edge, around which the pressures can become equalized. The difficulty lies in the fact that a strong suction must be generated on the upper side, only to vanish again at the trailing edge. From the point of least pressure on, the kinetic energy of the air must therefore be transformed into pressure by a gradual increase in the cross-section of the tubes of flow. There accordingly takes place, on the rear portion of the upper side, a phenomenon very similar to the flow through a widening tube.

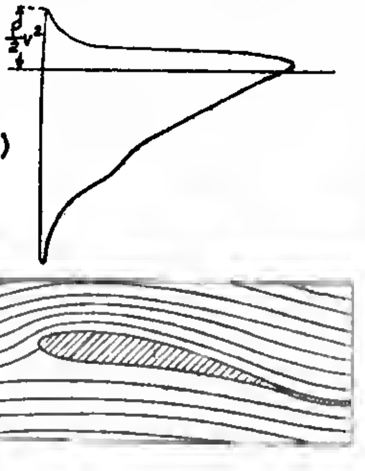
Now, it is known that such a flow, in which kinetic energy is transformed into pressure, remains stable only for a very gradual increase in the size of the cross-section. If the diameter increases too rapidly, the air does not continue to flow smoothly along the wall, but separates from it and goes its own way as a free jet, and the increased pressure is not obtained. If we increase the angle of attack of an aeroplane, the cross-sections of the tubes of flow on the suction-side are increased; and if a certain figure is exceeded, the air no longer flows along the upper surface of the wing, but is torn off, as it is expressed. This phenomenon is shown by Figs. 3 and 4. (The photographs were made by Dr. Heis and published in Prof. Prandtl's report on the Göttingen Aerodynamic Laboratory, in the Year Book of the Air Traffic Association, 1912-1913.) The first picture shows a wing having a normal angle of attack. The flow conforms quite



well to the top of the wing and is not seriously affected by the small vortices which cover the wing. With larger wings and greater velocities, the vortices are probably still smaller. The second picture shows the same wing at a somewhat greater angle of attack, in which case the fluid no longer follows the top of the wing.

Involuntarily we now ask how it happens that the air does not separate on even a moderate increase in the diameter of the cross-section. The explanation lies in the viscosity of the air or, in most cases, more correctly, in an apparent viscosity, which, in turbulent phenomena, is conditioned by the turbulence itself. The cause may be pictured qualitatively as follows: The

(b)



(a)

fluid has a tendency, on account of its inertia, to flow straight ahead, instead of following the curved surface, but then there must exist, between it and the surface of the wing, a quiet or an eddying "dead-water" region. This "dead water" is now carried along by friction (or the effect of viscosity) and must be constantly replaced (Fig. 4). Now, when the viscosity is so great that, in a given time, more fluid is carried away than can flow in, the "dead water" disappears and the flow follows the surface of the wing (Fig. 3).

Such are the general outlines of the phenomena which produce lift and which also limit its magnitude. Unfortunately these phenomena cannot be treated quantitatively by theoretical methods. We must therefore content ourselves with qualitative illustrations and will now endeavor to explain, on this basis, the action of the slotted wing.

For the sake of simplicity, we will assume that there is only one slot. Such a wing section may be imagined as a biplane with a very great positive stagger and a very small distance between the wings. Some justification for this conception proceeds from the fact that, even with an ordinary biplane, the maximum lift is increased by a positive stagger. According to biplane measurements published by myself in the fourth volume of "Zeitschrift für Flugtechnik und Motorluftschiffahrt." the maximum C_L without stagger was 100. with a positive stagger of 30° it was 110 and for one wing alone it was 106. Similar results were also obtained in England (Technical Report of the Advisory Committee for Aeronautics, 1915-16, Rep. 196. Sect. 11). Though the differences are not

* Reprint from "Berichte und Abhandlungen der WissenschaftlichenGesellschaft für Luftfahrt" (Supplement to "Zeitschrift für Flugtechnik und Motorluftschiffahrt"), No. 6, January, 1922.

Digitized by Google

great, they would evidently be greater, if the stagger were increased and the interval between the wings diminished.

We will first consider only the front wing and discuss how its characteristics are affected by the rear wing. From the theory of the biplane, we know that the flow is here obliquely upward. This affects the lift-drag ratio, but not the maximum coefficient of lift, which here alone interests us. We also know that, at this point, the flow forms a curve with the concave side up. This has about the same effect as increasing the wing camber. By increasing the latter, the maximum lift may actually be increased, though only to a very limited degree and at the expense of the lift-drag ratio. The rear wing is similarly affected by the curvature effect. It may therefore be assumed that the influence of the curvature of the flow plays a role of some importance with a given wing section with a moderately large camber, but nothing further is thereby gained than would be gained by a larger camber. The extraordinarily large increase in the maximum lift cannot therefore be thus explained.

The following consideration may be of more importance. The front wing lies in a region of increased velocity. Now, since the force of air is proportional to the square of the velocity, it is evident that the lift on the front wing is thereby considerably increased. This argument has but one exception, namely, that the reverse is true of the rear wing, so that for the combination of the two wings the two effects neutralize each other. In calculating the relations for an unstaggered biplane, we even obtain a smaller maximum lift than for the two wings alone and this result is confirmed by experiments. The relations are, however, somewhat changed by staggering. We must go into this more thoroughly.

We will first consider the arrangement with two wings of about the same size in which the relations stand out the clearest. The front wing, taken alone, would have a pressure distribution somewhat as shown by the fine line on the left of Fig. 5. Now, if we bring the rear wing, which has about the same pressure distribution by itself, into proximity with the front wing, the trailing edge of the latter will lie in a region of great velocity, and correspondingly small pressure, produced by the rear wing. The leading edge of the front wing, on account of its greater distance from the rear wing, lies in air that is much less disturbed and consequently in a region of nearly normal pressure. The leading edge of the front wing is, accordingly, not much affected by the pressure on the rear wing, while the pressure on the trailing edge of the front wing is diminished. We will therefore obtain, for the front wing, a lift distribution corresponding somewhat to the dash curve in Fig. 5.

Through this modification of the pressure curve, the pressure increase on the suction (upper) side becomes much flatter. On the other hand we know that the limit of the lift is determined by the steepness of the pressure curve. It is therefore evident that we may now further increase the angle of attack, until the inclination of the pressure curve again reaches its limit value (heavy line in Fig. 5). Since the velocity has become greater everywhere, the pressure curve may climb steeper than before.

As is obvious, the lift, which is represented by the area inclosed by this curve, has become considerably greater.

Let us now turn our attention to the rear wing. Here we find corresponding phenomena. The front wing produces on the leading edge of the rear wing a decrease in velocity and a consequent decrease in the

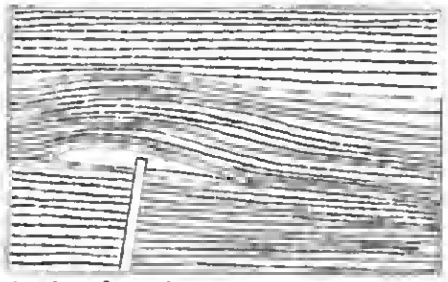


Fig. 3. Flow about a wing section at an angle of attack of 8°.

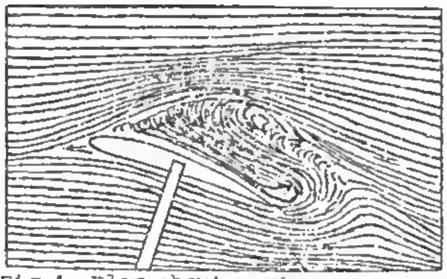

Fig. 4. Flow about a wing section at an angle of attack of 19°

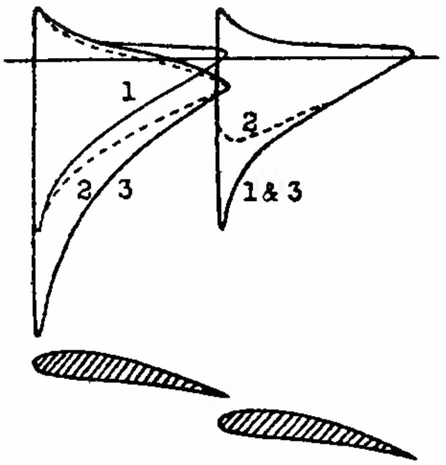
pressure diminution or suction. The trailing edge remains practically unaffected. Thus we obtain here, near the leading edge and mainly on top, an increase in pressure. The strong suction (or negative pressure) is diminished, so that here also there is a flatter pressure increase, as shown by the dash line. By increasing the angle of attack, we return approximately to the original curve, while the lift of the rear wing remains practically unchanged. Hence, in this combination the two wings produce a greater maximum lift than when separate, the gain being principally on the front wing.

The phenomena described will perhaps be more intelligible if we take for comparison the perfectly analogous phenomena of a simple and a compound Venturi tube. Fig. 6 shows a double Venturi tube, such as is often used on aeroplanes for measuring air speed. If we first imagine the small inside tube removed, we have a simple Venturi tube. The air flows through the constricted section with increased velocity and correspondingly diminished pressure. In the diverging cone behind it, the kinetic energy is again largely transformed into pressure, so that at the rear end, the external and internal pressures are again equal. Exactly the same causes which limit the lift in a wing, here make it impossible to obtain, by narrowing the throat, a pressure diminution of any desired value. In this case, however, it has long been known how to increase the suction by a suitable combination of tubes. Such an instrument is shown in the figure. The exit of the inner tube is at the point where a diminished pressure is already produced by the outer tube. The latter now forms the starting point for the further pressure diminution in the inner tube, just as in the case of the front part of the slotted wing section, which we have already considered.



We assumed in our discussion that the two parts of the wing were of about the same size. In practice, however, the front part is usually much narrower than the rear part. Our assumption that the pressures on the leading edge of the front part were not noticeably affected by the rear part, no longer holds true. Here the whole of the front section lies in a field of increased velocity and is thus able to produce a greater lift, since the lift is proportional to the square of the velocity. For the rear section, however, our previous remarks hold good. The disturbance due to the front section is felt principally on the leading edge, which therefore has approximately its normal lift. Accordingly, we even here obtain increased lift for the whole combination.

That the actual pressure distribution is approximately as described, follows from the data published by Handley-Page in "Engineering," March 4, 1921. These data are given in Fig. 7. For small angles ot attack, the rear section shows about normal lift distribution. The auxiliary wing in front gives only a small lift, since its angle of attack is much too small. Only from 12° up does the lift of the auxiliary wing show any considerable increase, while the pressure distribution of the main wing remains almost the same. The increased suction on the trailing edge of the auxiliary wing is also evident. At about 20°, the flow separates from the main wing and the lift of the auxiliary wing diminishes.

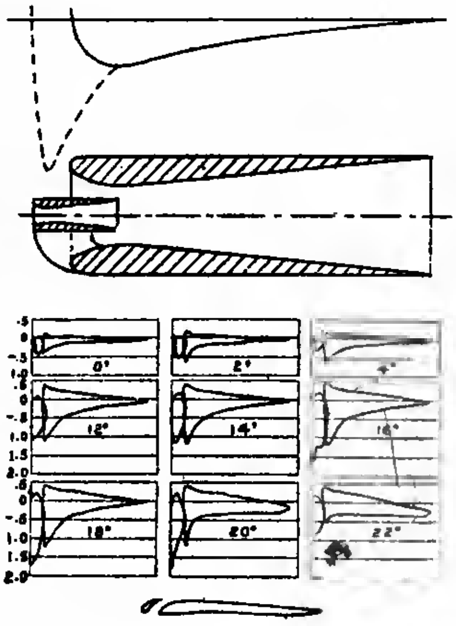
The above conception of the phenomena renders the occurrence of an increased lift coefficient somewhat more comprehensible and even offers the prospect of making it possible to compute the relations. On the other hand, the following consideration may be presented. If the slot is continuously narrowed, the arguments pointing to a higher maximum lift continue to hold good, but the phenomena vanish when the slot is closed altogether. This was to be expected from the first, since the wing is transformed by closing the slot into one of a practically normal shape. In any event, a slot of a certain minimum width is essential. Since the theory just presented, says nothing about this, the phenomena must also be considered from a different standpoint.

In explaining the phenomena of lift production, I called attention to the fact that the clinging of the air stream to, or its separation from, the upper surface of the wing depends on whether the dead air is carried off fast enough. When we consider this phenomenon on the rear section of a slotted wing, it is obvious that the work (which may be called pump-work or suction) must be performed at the expense of the kinetic energy of the thin air stream flowing through the slot. If the latter is made too narrow, the ribbon of air finally becomes so thin that its kinetic energy no longer holds out to the trailing edge of the rear section, but is, itself, transformed into dead air by mixing with the dead air above and below it. When considered from this standpoint, the phenomena of the slotted wing appear in quite another light. We can now think of this wing section as an entity, derived from an ordinary wing section by connecting its upper and lower surfaces by slots, which is, in fact, the con-

Digitized by Google

ventional conception. The slots convey new energy to the marginal layer of air retarded by friction on top of the wing, thereby increasing its velocity and thus preventing the accumulation of dead air. The air stream flowing out of the slot acts like the jet from a syringe and reinforces the air stream on top of the wing in carrying away the dead air. Since the production of lift depends on the efficiency of this pump-work and the maximum lift is conditioned by the limited possibility of carrying off the dead air, it is apparent that any increase in the pumping efficiency increases the maximum lift.

We are now inclined to ask which of these two theories is the right one. The answer is that both are equally correct, since they both explain the same phenomena, but from different standpoints. We should rather ask which viewpoint is the more practical. To this question I would reply that we have use for both, according to what we wish to learn. The conception of the slotted wing as a biplane whose wings mutually influence each other has the advantage of enabling computation to a certain extent. With its help, we may succeed in constructing formulas which will



enable the determination, in some measure, of the quantitative relations. The second viewpoint is essential, when it is desired to form an idea of the requisite width of the slot. I would add a word of warning against too great optimism. The relations are much more complicated here, than, for example, in the theory of the monoplane or biplane. Much work must still be done, before these theories are developed into practical rules. With the limited means now available, much time will be required for this work. The immediate task is to determine whether the theories just presented really explain the essential features of the phenomena, or whether other circumstances of decisive influence will come in. This cannot be conclusively determined from the experimental data now available. If the theory, however, agrees with the facts, this is already a great gain, even though we do not succeed in working out convenient computation formulas. We then know, at least, what the essentials are for obtaining the right shapes and can thus save ourselves much useless work.

(Translated by the National Advisory Committee for Aeronautics.)

ELIAS & BRO. PUT NEW COMMERCIAL PLANE ON MARKET

G. ELIAS & BRO., INC., of Buffalo, New York, on May 17 were awarded a War Department contract for two experimental machines of their design for a Type 12 Bomber, which was pronounced by the Department as the best plans submitted for the type specified. The Elias Company have received several awards for designs, notably these: June 1st, 1920—$3,000 prize for contract for three machines of their design for Air Service training planes; November 30th, 1920—$4,500 prize for the best three-seater multi-motor machine; June 28th, 1921—second prize for a ship-board plane, $10,000 by the Navy Department; August 2nd, 1921—$3,000 award for two-seater night observation plane.

Aside from these activities, G. Elias & Bro. have produced for the commercial market the Elias-Stupar aeroplane E-S-1 (biplane). It has 5 seats, including that of the pilot. It is designed to meet all requirements for commercial work; and the cost of operation is estimated to be 3.2 cents per pound load every 100 miles, 8 cents a passenger mile, with baggage; or 5 cents a passenger mile without baggage. Its cruising range with full load is 400 miles. There are 46 cubic feet of cargo space, with 14 cubic feet additional if necessary.

The following are approximate figures of cost of carrying cargo per 100 miles, based on an assumed distance of 300 miles between terminals:

Fuel and Oil	$ 9.00
Pilot	2.50
Upkeep (mechanics, spare parts, etc.)	11.00
Overhead (rental of field, telephone, office assistants, etc.) Based on a route where 5 machines are in use.	8.00
Depreciation and Insurance	2.50
Cost of transporting 1,000 pounds 100 miles	32.00
Cost per pound per 100 miles	3.2c

Other specifications are:

Spread	34 ft. 5¾ in.
Length	24 ft. 4 in.
Height (tail on ground)	9 ft. 4 in.
Height (fuselage level)	9 ft. 8 in.
Total Wing Area (including ailerons)	385 sq. ft.
Aileron Area	51 sq. ft.
Horizontal Stabilizer	20 sq. ft.
Vertical Stabilizer	7 sq. ft.
Elevators	25 sq. ft.
Rudder	14 sq. ft.
Gap	5 ft. 6 in.
Chord	5 ft. 6 in.
Gap Chord Ratio	1 to 1
Dihedral between motors	0°
Dihedral overhang	2°
Angle of incidence relative to center line of propeller shaft	3°
Angle of incidence with tail skid on the ground	17°
Power	2-80 h.p. LeRhone
Motors	160 h.p.
Fuel capacity	86 gals.
Oil capacity	12 gals.
Seating capacity	5
Baggage space—in addition to passenger compartments	10 cu. ft.
Total cargo space when no passengers are carried	46 cu. ft.
Weight, empty	1569.52 lbs.

Non-pay useful load, consisting of:		
Students control	4.50	
Cushions, except pilot's	36.69	
Safety Belts, except pilot's	6.00	
Fire Extinguishers	20.00	
Gasoline (3 hr. supply)	360.00	
Oil (3 hr. supply)	72.00	
Pilot	162.00	
Total	675.88	
Pay load	955.60	
Total useful load		1631.48
Total weight of machine fully loaded		3200.00
Light load (definition) Minimum weight of machine for one-half hour flight, consisting of:		
Weight of machine empty	1568.52	
Pilot	160.00	
Fuel for one-half hour	60.00	
Oil for one-half hour	12.00	
Total		1800.52

Wing loading, light load (1800 lbs.)	4.80 lbs. a sq. ft.
Wing loading, full load (3200 lbs.)	8.55 lbs. a sq. ft.
High speed, light load	90 m.p.h.
High speed, full load	90 m.p.h.
Landing speed, light load	35 m.p.h.
Landing speed, full load	50 m.p.h.
Climb, full load	400 ft. per min.
Climb, light load	1000 ft. per min.

STABILITY OF AEROPLANES

By EDWARD P. WARNER

Professor of Aeronautics, Massachusetts Institute of Technology*

THERE is a very general misunderstanding about the amount of skill and natural aptitude required for flying an aeroplane. One often lnds an impression among persons not directly associated with aeronautics or in a position to be kept informed of advances in that science that the operation of an aeroplane is somewhat analogous to walking a tight rope, and that the piloting of such machines is possible only for those who have the natural aptitudes of the trick bicycle rider or the aerial acrobat. As a matter of fact, of course, flying is extremely easy. In many ways it is easier than driving an automobile, and any sound person can learn to fly at least fairly well, if not to be a pilot of exceptional skill.

The popular misconception regarding the difficulty of flying arises largely from the belief that the aeroplane is an essentially unstable vehicle and that it is continually watching for a chance to get out of equilibrium and hurl its unwary pilot to his doom. While such strictures might have been justified, at least to a slight extent, in connection with some of the early aircraft, there is no reason for them now, as the modern commercial or touring aeroplane is extremely stable and steady in flight. It not only does not deliberately depart from its normal course but even resists any attempt to make it do so. In fact, some aeroplanes are so stable that pilots object to them on the ground that it is impossible to make them fly in an abnormal position when that is necessary for the purposes of a particular maneuver.

Automatic Pilots

Such stabilization does not require the use of any elaborate mechanical device. In the early days of flying all sorts of schemes, most of them involving pendulums and gyroscopes, were proposed and tried and some succeeded very well in stabilizing the aeroplane or at least in exercising the functions of the pilot, relieving him of the duty of operating the controls. It should be emphasized, however, that the mechanism merely operates the controls, and that no such thing as a true stabilizer, operating directly on the aeroplane as a gyroscopic stabilizer acts on a ship, has yet been produced. A real stabilizer, at least if it were of the gyroscopic type, would be far too heavy to be carried in flight. Some of the devices for keeping an aeroplane on an even keel are already described by their inventors as automatic pilots or mechanical pilots, rather than as stabilizers, and it would be well if the same terminology were to spread to all the other cases.

No automatic pilot has gained any real wide measure of favor. The difficulty of piloting is not great enough to require the intervention of any new devices, especially since they do not relieve the pilot of his most difficult task, that of making a landing. Pilots have a natural distrust of any new mechanism and hesitate to permit the introduction of an instrument, the multitudinous gears and levers hidden away from inspection, on whose continued perfect functioning the pilot's life must hang. They far prefer to depend either on their own skill and watchfulness or on the natural stability of the aeroplane secured by the form and disposition of its rigid parts.

Stable Designs

A skillful pilot can fly an unstable aeroplane successfully. Quite aside from this fact, however, there really is no need for elaborate mechanisms such as are frequently produced, as it is not difficult to make any desired degree of stability inherent in the aircraft, arising from the very design of the machine. In fact, the point has been reached where it is possible to lay down a few simple rules which suffice to insure stability, at least in longitudinal motions. To prevent pitching an to insure that it will not attain a dangerous magnitude is far easier than to prevent the aeroplane becoming unstable in roll. Although the most uncomfortable oscillations of an aircraft are those in pitch, the aeroplane being unlike a ship in this respect, there is little danger from such oscillations if the slightest attention was given to stability in the design.

Stability in roll, however, and the securing of directional stability, or the tendency to maintain a straight course and to resist any tendency to go into a turn, are much more difficult to secure and the problems connected with them are not yet fully understood. The most frequent cause of accident is still the spin, a particular form of lateral instability. Aeroplanes have been built which were "spin-proof," which would never assume a spinning attitude of their own accord, but the means by which that much to be desired characteristic was obtained are not yet clear enough to make possible their certain duplication on another design.

Reliance in Mathematics

The study of stability and its improvements on given types of aeroplanes is one of the most important in connection with which further study is required. Development in this direction can come only through the enthusiastic cooperation of the aeroplane designer, the experimenter in the laboratory or in free flight, and the mathematician to whom the theory of the subject is due. It cannot be too strongly emphasized to those who do not already know it that the whole procedure in designing stable aircraft is based on a mathematical theory originally produced by pure mathematicians and physicists, some of whom had never had the slightest experience in flight. That it is now possible to produce an aeroplane which can be flown for long periods without touching the control is due largely to the genius and patient labor of Professor Bryan and Dr. Leonard Bairstow and others in England and of Prof. E. B. Wilson and Commander Hunsaker and their co-laborers in other countries.

Mathematical analysis alone, of course, does not suffice, and the practical application of mathematics must rest on data obtainable in part in the wind tunnel or laboratory, in part only in flight. The most effective check on any deductions regarding stability is obtained hy making a succession of changes in an aeroplane and actually observing the effect which they produce on stability. Such work has been and is being done by the Royal Aircraft Establishment in England and by the National Advisory Committee for Aeronautics here, and on it no less than on the labors of the mathematician the production of safe and stable machines in the future must rest.

The final problem is to secure the devoted cooperation of the aeroplane designer. It is a lamentable fact that there yawns too often a wide gulf between the "theorist" and the "practical man," a gulf across which each party regards the other with scorn. The problems are too great to permit of any dissension as to who shall work on them, and the best results will be obtained only when the designer makes full use of the work of the experimenter and the mathematician and when those individuals of more theoretical bent carry on their labors with the actual practical needs of the designer constantly in mind.

AMERICA READY FOR AIR TRAVEL

AT the ninth bi-monthly luncheon of the Aeronautic Executives, held at the Cafe Boulevard, New York, May 8, Major B. L. Smith, General Manager of the Aeromarine Airways, Inc., proved conclusively that there was adequate and efficient aircraft equipment at present in operation in this country to operate extensive air routes throughout the U. S. if public interest was sufficiently aroused.

In introducing Major Smith, Chairman R. R. Blythe stated that the Major was a pioneer naval aviator who had been flying since 1911. It was through his efforts, to a very great extent, that a branch of Naval Aviation was organized in America. During the war Major Smith won high recommendations from the Allied Air Forces for his efficient organization and operation of naval aircraft.

In the operation of the Aeromarine Airways between Key West and Havana and the Nassau-Bimini-Miami route there was a total number of 747 flights made over a period of six months, during which time there was carried 2,700 passengers and 10,800 pounds of freight.

"Of course, I am very enthusiastic about the results of our Southern operations, and aided us in making this very favorable owing to the fact that the tourist season record, we expect next year to even exceed the number of passengers and freight carried by a large percentage.

"The fact being that the public now realizes that there is a very much improved service between Key West and Havana which eliminates the eight-hour steamship trip across the 97 miles of open, and very often rough, ocean. This trip is made by air in one hour and fifteen minutes.

"During the 2,100 flying hours in the South," said Major Smith, "we have proved conclusively that commercial aviation is safe and that a commercial aircraft com-

Digitized by Google

pany can be operated at a profit. One of our F5L's, the 'Ponce de Leon,' during two months made over 100 miles daily, and every third day completed a round trip from Key West to Havana, a distance of 200 miles. There were no accidents, but one wing tip pontoon was lost, the cost of replacement being about $148.00.

"We have operated through all kinds of weather and have a record of only three interrupted flights during our total season of operations.

"For a commercial seaplane there is not today a safer, more durable or commodious plane than the F5L. It is strong enough and sufficiently seaworthy to ride on the buffeting ocean waves which would swamp and sink a smaller plane.

"During the operations of these boats we have had the Santa Maria in the water as long as nine months. Even after the trying 7,000-mile flight last summer from Key West to New York over the Great Lakes to Chicago, down the Mississippi to New Orleans and back to Key West through many varying temperatures, the highest being 103 degrees in the shade, we had only to recover the wings and make some small paint retouching to the hull and tail section. The maintenance cost is extremely low on this type of plane. Of course, much of this is due to the care in operation and handling.

"Docking after flights presents most causes for injury to the craft, due to missing the mooring and drifting into the wharf or bumping the wings and hull. Even this feature is not serious, because the total costs for damage caused in docking would not amount in six months to sufficient to increase our regular pay-roll or supply orders.

"On July 1 we begin operations of a round trip daily between New York and Atlantic City with a 14-passenger flying boat, making this trip in 1 hr. and 15 minutes. This plane leaves 79th Street and Hudson River at 4:00 p. m.

"We will also inaugurate on the same date our Cleveland-Detroit daily service, making the trip in 90 minutes which takes 7 hours by rail."

Major Smith referred to the lack of public patronage of aerial transportation by the brief statement that the publication of the crash of the London-Paris aircraft featured in the Sunday papers decreased the gross income for passenger flights on the same day exactly 100% over the previous daily income.

"I am sure that if we only were given the publicity in the newspapers which has been devoted in the past to feature crashes and had in their place stories of sane aircraft operation, we would today be in a position to give daily air service anywhere in the United States for those who wish to cut traveling time in half, and that by this patronage the rates charged, which now seem extremely high, would be in turn only slightly in excess of that charged by railroads."

Among the aeronautic companies were represented the Aeromarine Airways, Inc., Gallaudet Aircraft Corporation, Netherlands Aircraft Mfg. Co., Wright Aeronautical Company, Curtiss Aeroplane & Motor Corp., J. L. Aircraft Corp., Loening Aeronautical Engineering Corp., American Airways, Inc., and Johnson & Higgins, Aeronautical Insurance Brokers.

SYLPHON DIAPHRAGMS

A Method for Predicting Their Performance for Purposes of Instrument Design

By H. N. EATON and G. H. KEULEGAN

Bureau of Standards

Introduction

THIS technical note was prepared for the National Advisory Committee for Aeronautics as a part of the report on the "Investigation of Diaphragms for Aeronautic Instruments," and the purpose of this paper is to show that the characteristic performance of a sylphon diaphragm can be predicted from a knowledge of its stiffness and of its dimensions. The proof is based on a mathematical analysis of this type of diaphragm, together with enough experimental data to prove the validity of the assumptions and the sufficiency of the analysis. Equations are developed for the performance of sylphons under various conditions of loading, both for concentrated loads and for hydrostatic pressure.

The results of the investigation will be useful in the design of instruments or devices containing sylphons, since, by measuring certain dimensions of the diaphragm and the deflection produced by a known concentrated load (to determine the stiffness), the designer will be able to predict the action of the sylphon under the above-mentioned types of loading within the limits defined below.

The load-deflection curve of a sylphon is linear over a considerable range, and over this range the errors due to imperfect elasticity (i.e., drift, hysteresis, and after-effect)* have been found to be less than 1 per cent of the maximum deflection and so can be neglected, as far as the object of this paper is concerned. The discussion which follows is limited, therefore, to the range of loading for which the load-deflection curve of the sylphon is a straight line and does not include a consideration of the effect of drift, hysteresis and after-effect.

Assumptions

The following assumptions will be made:

(a) The load-deflection curve of the sylphon for concentrated loads is linear. (This curve will be called the *characteristic curve* of the sylphon—see Fig. 2.)

(b) The errors due to imperfect elasticity (drift, hysteresis and after-effect) can be neglected.

(c) The external space between two successive corrugations is equal in volume to the internal space between two successive corrugations for deflections within the linear range.

(d) The cross-sectional area of the sylphon remains constant.

It has already been stated that assumptions (a) and (b) are warranted from experimental evidence. The range over which they hold good will be discussed later for a particular sylphon.

Assumption (c) is justified by the excellent agreement between results obtained experimentally and those obtained analytically by making use of this assumption. Assumption (d) is sufficiently accurate for the present purpose.

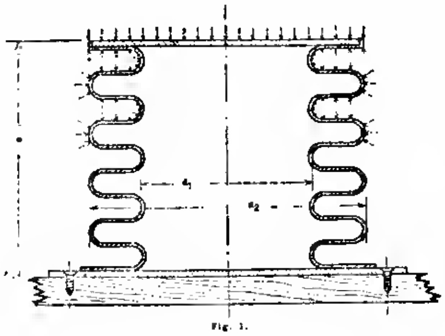

Fig. 1.

Notation

The following notation will be used:

L = concentrated central load.

P = difference of pressure between inside and outside of sylphon.

d_1 = internal diameter of sylphon. (See Fig. 1.)

d_2 = external diameter of sylphon. (See Fig. 1.)

y = deflection of upper face under load, measured from neutral position of upper face (i. e., under no load).

A = maximum cross-section perpendicular to axis $\left(\text{i. e., } A = \frac{\pi d_2^2}{4}\right)$

A_e = equivalent area.

l = length of sylphon.

h = depth of one corrugation.

V = volume of the sylphon.

v = average volume of sylphon per unit length $= \frac{V}{l}$.

W = work done on or by the sylphon.

n = number of corrugations.

S_s = spring stiffness $= \frac{L}{y}$

S_c = stiffness of sylphon for concentrated loads $= \frac{L}{y}$

S_d = stiffness of sylphon for distributed loads $= \frac{P}{y}$

S = stiffness of combined sylphon and spring when hydrostatic pressure is supplied to the sylphon.

g = width of gap between spring and sylphon before being coupled together.

---

* These terms will be defined as follows:

Drift is the change of displacement under constant load.

Hysteresis is the excess of displacement with loads decreasing, over the displacement at the same load, with loads increasing.

After-effect is the residual displacement at any time after removal of the load.

Digitized by Google

THEORETICAL DISCUSSION

Laws of Deflection

Consider a sylphon diaphragm with its axis vertical, its lower surface fixed, and with its upper surface consisting of a rigid plate (see Fig. 1). When concentrated loads are considered, it will be assumed that they are applied vertically at the center of the rigid plate. The discussion which follows applies only to the range of deflections for which the load-deflection curve is linear.

From assumption (a) and the definition of stiffness there follows:

(1) $L = S_c y$.

It will now be proved that a relation

(2) $P = S_d y$

similar to that expressed by equation (1) exists for loads produced by hydrostatic pressure.

Consider the system consisting of a sylphon with an applied concentrated load L. The interior of the sylphon is open to the outside air. While the sylphon is yielding to the influence of this load, the effective force, i. e., the force tending to deflect the sylphon, is $(L - S_c y)$. Hence during the infinitesimal distance dy the work of deformation is $(L - S_c y)\, dy$. The total work of deformation or the increase in potential energy of the system when the deflection has reached a value y_1 is

$$(3)\quad W = \int_{y=0}^{y=y_1} (L - S_c y)\, dy = L y_1 - \frac{1}{2} S_c y_1^2 = \frac{1}{2} S_c y_1^2$$

Now suppose a hydrostatic pressure P applied to the sylphon tending to nullify the deflection produced by L. Then if y is the deflection of the sylphon measured from its original position under no load, we can express P as a continuous and single-valued function of $y_1 - y$ as follows. Denote $y_1 - y$ by D.

(4) $P = A_1 D + A_2 D^2 + \ldots\ldots\ldots A_n D^n$

where $A_1, A_2, \ldots\ldots\ldots A_n$ are constants.

Suppose that P is taken sufficiently great exactly to nullify the deflection produced by L. During the cycle just completed, no unconservative forces have been introduced if we neglect the hysteresis and internal friction in accordance with assumption (b) and ignore the small effect due to viscosity of the air. Consequently, when the deflection has been reduced to zero by the application of the pressure P, the work thus done can be equated to $\frac{1}{2} S_c y_1^2$, the potential energy which was added to the system when it deflected under the influence of the load L.

Therefore,

$$(5)\quad W = \int_{D=0}^{D=y_1} KPdD = \int_{P=0}^{P=P_1} PdV = \frac{1}{2} S_c y_1^2$$

Substituting from (4) the value of P,

$$W = \int_{D=0}^{D=y_1} K[A_1 D + A_2 D^2 + \ldots A_n D^n]\, dD = \frac{1}{2} S_c y_1^2$$

or

$$(6)\quad W = \frac{KA_1 y_1^2}{2} + \frac{KA_2 y_1^3}{3} + \ldots$$

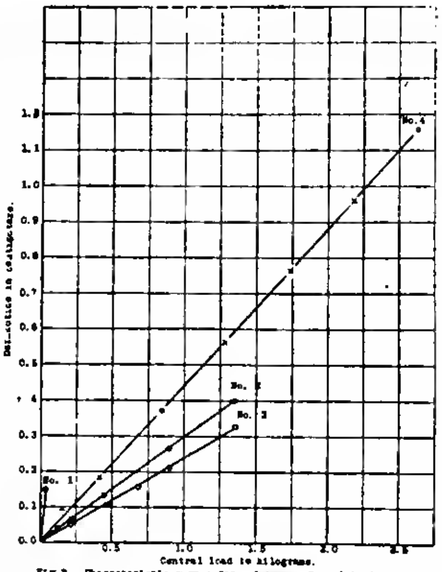

Fig. 2. Characteristic curves for sylphons. Nos. 1 to 4.

$$\frac{KA_{n-1}\, y_1^n}{n} = \frac{1}{2} S_c y_1^2$$

This equation must hold for any value of y_1; hence the coefficients of y_1^n must vanish identically; i. e.:

$$(6a)\quad \begin{cases} KA_1 = S_c \\ \text{and } A_2 = A_3 = \ldots\ldots A^n = O \end{cases}$$

Equation (4) now becomes

$$(4a)\quad \begin{cases} P = A_1 D \\ P = A_1 (y_1 - y) \end{cases}$$

Since we are considering only the linear portion of the deflection curve of the sylphon, it makes no difference where the initial position is taken; consequently (4a) may be written

(4b) $P = A_1 y$

where y is now measured from the position of the upper surface of the slyphon before the pressure P was applied. If we replace the constant A_1 by S_d, (4b) becomes identical with (2) and thus proves the validity of the letter. Experiment also verifies equation (2) (see Fig. 3).

EQUIVALENT AREA

Dividing equation (1) by equation (2) there results

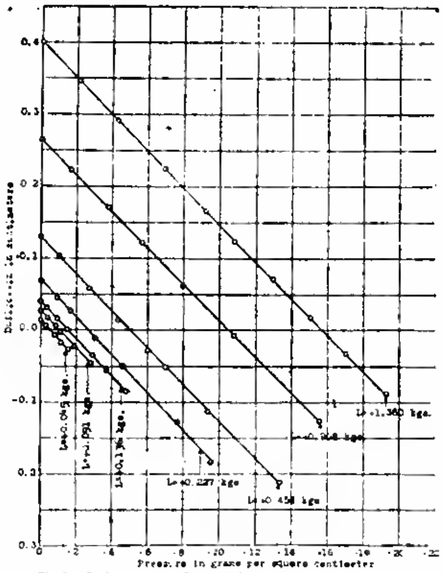

Fig. 3. Deflection of sylphon No. 2 with variable pressure under constant central load

$$\begin{cases} \frac{L}{P} = \frac{S_c}{S_d} \\ L = P\frac{S_c}{S_d} \text{ (y constant)} \end{cases}$$

Now the ratio S_c/S_d has the same dimensions as has area. It is also clear that this ratio for a given sylphon is dependent only on the geometrical and physical characteristics of the sylphon. Consequently it may be considered as a certain proportion of the maximum cross-sectional area A of the sylphon and will be called the *equivalent area* of the sylphon. The physical significance of the equivalent area may be seen most clearly perhaps by considering that a given hydrostatic pressure P produces the same deflection of the sylphon as does a certain concentrated central load L, and that the equivalent area is defined as the ratio of this L to the given P. Its usefulness consists in the facts that it is a constant for a given sylphon and that it enables one to predict the performance of the sylphon under any specified conditions, once the deflection for one concentrated load is known. The value of the ratio S_c/S_d or A_q will now be derived in terms of known constants and dimensions of the sylphon.

Returning to equation (5) we have

$$(5)\quad \int_{P=0}^{P=P_1} PdV = \frac{1}{2} S_c y_1^2$$

$$dV = d\,(lv) = vdl^* = vdy$$

and

$$P = S_d y \text{ from (2)}$$

$$\therefore \int_{y=0}^{y=y_1} S_d v y\, dy = \frac{1}{2} S_c y_1^2$$

or

$$\frac{1}{2} S_d v y_1^2 = \frac{1}{2} S_c y_1^2$$

whence

$$(8)\quad \frac{S_c}{S_d} = A_q = v$$

Now v may be computed from the assumption that the sylphon is made up of successive cylinders each of height h and alternately of diameter d_1 and d_2.

If there are 2n corrugations then

$$v = \frac{V}{l} = \frac{\pi nh\,(d_1^2 + d_2^2)}{2nh} = \frac{\pi}{8}(d_1^2 + d_2^2)$$

or

$$(9)\quad A_q = \frac{\pi}{8}(d_1^2 + d_2^2)$$

Experimental verification of this result will be given later.

For purposes of comparison it will often be convenient to express the equivalent area as a percentage of the maximum area. Thus,

$$(10)\quad \frac{A_q}{A} = \frac{(d_1^2 + d_2^2)}{2d_2^2}$$

$$(10a)\text{ or } 100\frac{A_q}{A} = 100\frac{(d_1^2 + d_2^2)}{2d_2^2} \text{ per cent}$$

*See assumption (c).

PERFORMANCE OF SYLPHON

From equations (1), (2,) (7), and (8).

(11) $L + A_q P = S_c (y_1 \pm y_2)$

where y^1 is the deflection produced by L and y_2 is the deflection produced by P.

Equation (11) contains two constants, A_q and S_c, which depend only upon the characteristics of the sylphon. A_q can be computed from purely geometrical considerations, but S_c must be determined by

Digitized by Google

experiment. From a single deflection with a concentrated load it is possible to obtain S_c, provided care is taken that the range of loading for which the load-deflection curve is linear is not exceeded. It is also possible to determine A_q from a second experiment with distributed load, but it is usually preferable to compute the value of this constant from equation (9).

Performance

Suppose that a sylphon is distended by a spring either internal or external (see Fig. 4). The performance of the spring may be expressed by

(12) $L = S_s y$

Assume that, with the spring and sylphon mounted but not coupled together, there exists a gap g between the couplings. If the two are now coupled together, g is reduced to zero and the top of the sylphon is deflected an amount y_1. y_1 can be computed from the known values of g, S_c, and S_s and, consequently, the reaction of the spring and the sylphon upon each other L_a can be computed, as will be shown.

$$L_a = S_c y_1 = S_s (g - y_1)$$

$$(13)\left\{\begin{aligned} y_1 &= \frac{S_s g}{S_c + S_s} \\ g - y_1 &= \frac{S_c g}{S_c + S_s} \end{aligned}\right.$$

and

$$(14)\quad L_a = S_c y_1 = \frac{S_c S_s}{S_c + S_s} = g$$

Now let a pressure P be applied externally (or suction internally). Equating the force exerted by the spring to the elastic resistance of the sylphon and the load, there results

$$L_a + S_s y = L_a - S_c y + A_q P$$

where y is measured from the neutral position of the couplings when the sylphon and spring are coupled together.

Then (15) $A_q P = (S_c + S_s)\, y$

or

$$(15a)\quad P = \left(S_c + \frac{S_s}{A_q}\right) y$$

The quantity in parentheses is the stiffness of the combination of spring and sylphon and (15a) may be written

(15b) $P = Sy$

Four sylphons were tested in order that experimental confirmation of the preceding analysis might be obtained. The construction characteristics of these sylphons are given in the following table:

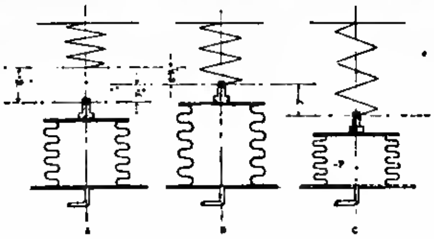

Fig. 4. Sylphon and spring in combination.

TABLE 1.

Material (Brass)				

Fig. 2 shows the characteristic curves for these sylphons. The value of S_c can be obtained from these curves, since from

$$(1)\quad S_c = \frac{L}{y}$$

Fig. 3 shows performance curves for Sylphon No. 2 determined experimentally. Extension and loads tending to produce extension of the sylphon are considered positive. The curves are linear over the range shown in Fig. 3. It was found that, when a load producing a deflection of —0.35 cm. was applied, the curve was no longer linear. The points in which the lines L = const. cut the axis of deflections is obtained from the characteristic curve of the sylphon. The points in which these lines cut the axis of pressure may be computed from equation (11) by putting $y_1 - y_2 = 0$, when

$$P = \frac{L}{A_q}$$

or, if preferred, the lines may be drawn through the proper points on the axis of deflection with the required slope. This slope is easily proven to be $+S_c$ from equation (11). The slope appears to be negative in Fig. 3, but it should be remembered that the pressures shown here are negative.

Fig. 3 shows that Sylphon No. 2 will give linear load-deflection curves from a deflection of about —0.2 cm. to at least +0.4 cm. The positive limit of linear deflections may be much higher than +0.4 cm., but the tests were not carried to the limit.

From a consideration of the way in which the family of curves in Fig. 3 was constructed, it is clear that each intersection of a line L = const. with the axis of pressures can be used to determine the value of A_q. Considering such a point we have the relation

$$A_q = \frac{L_1}{P_1}$$

This will be utilized to provide a check on the values of A_q as determined analytically.

Av.			88.58	83.4	83.8

The difference is 0.5%.

The agreement between the experimental and calculated values of A_q indicates that the equivalent area for any sylphon is independent of the elastic properties of the sylphon and may be computed from the expression

$$A_q = \frac{\pi}{8}\left(d_1^2 + d_2^2\right)$$

METAL CONSTRUCTION

By Rodolfo Verduzio*

Director of the "Instituto Sperimêntale Verduzio"

THE future development of aerial navigation is closely connected with the condition of obtaining aeroplanes of great stability and sufficient strength. Formerly, the science and technical knowledge of construction were deficient and the difficult problem of the necessary lightness for being supported by an element so thin as air was solved at the expense of the strength of the entire structure. This beginning, which has led to great and undoubted progress, has resulted in many accidents, and thus every advance has been accompanied by a series of mishaps. The evolution of aircraft has been quite rapid, but not so rapid as human evolution. The technician obtained a slight structural improvement, which the pilot recognized, appropriated and utilized to its fullest extent, and then sought something better. At the same time, he became more skillful and bolder, and tested the aeroplane more severely, so that it often gave out because it lacked just what the hand that guided it required. Thus it became necessary to make aerodynamic modifications and structural reinforcements. Abstaining for the present from taking up the problem of aerodynamic progress, we will consider the problem of structural strength.

The coefficient of safety, that number which represents in all structures the ratio between the breaking strength of a part and the load or stress which it must normally withstand, was quite a small number for the first aircraft. The poor constructor struggled with his own ignorance and his lack of adequate means. His aeroplane had neither suitable finish of form nor materials of suitable strength and lightness nor reliable engines, powerful and light. Hence they were heavy, clumsy, slow, and not very strong. But with such ill-adapted means, laws were determined, flights were made, and the course to be followed was outlined. Progress was made

* Lecture delivered before the "Associazione italiana di aeronautica."

Digitized by Google

which, by gradually eliminating the defects due to ignorance, has reached its present state. This state is not the final condition, but simply a step to be used as the basis for still greater progress. Today the former modest coefficient of safety has been considerably raised, and is at least 10 for a swift aeroplane, and 6 or 7 for some parts of a good airship. These numbers, which have not yet been reached in most other kinds of construction, are not, however, the maximum limits for aeronautic construction. Pilots still demand much in the way of technical improvements.

The idea here promulgated seems contrary to the general opinion. How much more solid a house or a locomotive seems than a light aeroplane' How much more solid an automobile or a ship seems than a fragile airship! Nevertheless, the house, the locomotive, the automobile, and the battleship have no greater coefficient of safety than is required for the modern aircraft.

The need of a very high coefficient of safety resides in the nature of the aeroplane which, being balanced in the air, is capable of great acceleration from the application of great forces which necessitate coefficients greater than any hitherto obtained and which, for some aircraft, can technically assume such high values as to render their construction impossible. Able technicians are today trying to solve the intricate problem and some carry their conception to the point of claiming that the coefficient of solidity of some aircraft can be even a little higher than that of its pilot. Experiments have already been suggested for determining the coefficient of human stability, a coefficient which, for our satisfactions, we may consider from various indications as being quite high.

The very high value of the coefficient of safety now necessary demands the most accurate construction, worked out in its minutest details with materials of the very best quality—a construction which, in order to be light enough, must correspond perfectly to the theoretical conception and, in order that every part will function exactly as designed, every secondary stress must be eliminated and every harmful strain avoided. In general, for every flexure there is a corresponding adjustment favorable to the stability, at least when it is a question of a part being loaded to the point where any distortion indicates the beginning of excessive flexure with consequent collapse. But structures consisting of members loaded axially are ordinarily the lightest and are therefore preferred in aeronautics. Therefore every failure must, in general, he confined within the narrow limits indispensable for the strength of the member involved. The distortions correspond to the moduli of the elasticity and hence are of the greatest importance in selecting the materials to be used in aeronautics. It is not necessary to exclude all materials of great elasticity (the wood for propellers may be all the more desirable on that account), but with a low specific gravity, great strength, a high limit of clasticity and a high coefficient of expansion, there is generally combined a high modulus of elasticity.

After having thus characterized the mechanical properties of aerodynamic materials, we can immediately separate them into two categories. One category includes all those employed in parts requiring continuity of material and which may consist either of a simple covering, or also at the same time of a strong member. The other category comprises all materials especially adapted for strong parts. In this second list, on account of the mechanical properties of the materials, there is found natural extrinsicality and perfect correspondence. In the first list, on the contrary, the condition of continuity makes itself imperiously felt and to this requirement there must often be joined that of flexibility. As things are now, we would be unable to imagine an airship not covered with fabric, or its car not covered with fabric or a thin layer of wood, but, if (aside from the specific case of the envelope of an airship to which we will shortly recur) we concede that the element of shape serves a purpose, we can best employ a covering without flexibility and we can imagine a car, a fuselage, or a wing not covered with fabric, but made of strong material or metal sheets.

The case of the airship is somewhat different from the examples just mentioned, on account of the enormous size of the envelope, which, in order to be strong enough, necessitates the concentration of certain stresses in strong members, which could not be distributed along the whole surface, so that although the resistance to the normal stresses would be possible theoretically, there would still be failures due to secondary and local stresses. The non-rigid envelope is flexible by nature and withstands the stresses by reason of the tension of the inclosed gas, which renders it sufficiently rigid since any force of compression at any point is always less than the pre-existing tension.

Aside from the canvas used especially for airships, the aeronautic materials which we may term non-flexible* and which are used in constructing the framework of aircraft, are: iron, with its binary and ternary alloys; aluminum with its alloys, and wood. To these must be added those which are used for bushings, supports, etc., but these materials, on account of their heavy weight are used in small quantities and only where they are indispensable.

Wood, aluminum, iron and alloys were not equally employed during this period in the various parts of aircraft. The progress in construction made in aeronautics before the war was due almost wholly to the iron and metal industries. These gave us the indispensable powerful and light engines. The first aircraft employed much steel, considerable aluminum and some wood. With the advent of the war there was a great and increasing consumption of metals in war materials, leaving little for aeronautics. This fact, together with the shortage of good mechanics, led to the extensive use of wood and the limitation of metal to those parts where it was found to be indispensable, all the more, because the disadvantages due to the conservation of articles of wood were not felt during the war on account of the necessarily rapid renewal of war material. The problem now has quite a different aspect. The commercial problem has come to the front, and aeroplanes, hesides being safe, must be able to make long trips. Wood presents disadvantages possessed in only a small degree by metals: distortion, due to its low modulus of elasticity; excessive deterioration, from inclement weather; possibility of breaking easily from splitting; lack of homogeneity in density and strength, and ease of absorbing moisture, which diminishes its strength. Hence, as in all other construction wood has gradually yielded to metal, a like change is taking place in aircraft. It is well to remember that the advantage claimed for wood, of greater strength in proportion to its weight, no longer has any value, since I have already shown in a different article (in "L'Aeronautica," March, 1920) that good steels, duralumin, and alloys are, even in this respect, preferable to the best woods for aircraft. We will now make a little closer study of metal construction.

Fully loaded parts not exposed to the wind.—Steel and, to a smaller degree, aluminum and duralumin tubes are suitable for small loads borne for comparatively short periods. Theoretically, this is shown by a formula which includes the thickness, diameter of tube and length loaded or stressed.

1. *The minimum thickness is determined by conditions of indeformability from secondary stresses.*—Both theoretically and practically it has been demonstrated that this minimum thickness is a function of the radius of curvature, and it appears that the minimum thickness should never be less than 1/20 of the radius of the cross-section of the tube. Under these conditions, we assume that we can adopt, for good carbon steels, or ternary steels of 50 to 60 kg. per sq. mm. breaking strength, a safety load of about 1/5 of the breaking strength, while for duralumin the safety load must be kept somewhat lower, probably about 1/7. When subjected to severe tests, such tubes have demonstrated the perfect agreement of the practical results with the theoretical deductions. In Fig. 1 are shown the distortion curves of several tubes which were tested, and it may be seen how little the values registered vary from the distortion curves.

These tubes are not strong enough, however, for great loads and lengths. In such cases recourse is had to complex construction with braced girders. The theoretical conception is simple, but the external construction assumes various aspects. Ordinarily (Fig. 2) three similar members are parallel to the axis of the compressed solid and are connected with one another in various ways, which give the various methods of construction. Thus the steel tubing girders of the first Italian airships were very similar to those used in the Zeppelins (Fig. 3). Not all the connections were suitably made and we improved the construction of the various joints, thus obtaining greater strength for the same weight, and giving us the steel girders (Fig. 4) of our present airships and the dulalumin girders (Fig. 5). The principal difference between the steel and duralumin girders lies in their joints. For the former a good fastening with iron wire or tin solder (Fig. 6) answered the purpose, while the latter had to be joined with at least two rivets (Fig. 7), which necessitated the use of sheet metal members instead of tubes. Aside from the above mentioned manner of bracing, other methods have been employed with equally good results, as shown in Figs. 8, 9 and 10, representing both square and flat girders.

We also show here some results (Fig. 11) of breaking tests. Note how accurate the agreement is hetween the experiments and the theory. Every distortion could have been perfectly predicted.

(*To be concluded*)

* There are also elastic rubber cords which are used as shock absorbers and recall springs.

NAVAL and MILITARY AERONAUTICS

Chief of Air Service Flies Over Capitals of Three States

By utilizing the airplane, General Mason M. Patrick, Chief of Air Service, was enabled to save several days' time in his inspection trip of fields in the 4th Corps Area. Air Service activities were inspected at Chapman Feld, Miami, Fla.; Carlstrom and Dorr Fields, Arcadia, Fla.; Americus, Ga.; Montgomery, Ala.; Camp Benning, Ga.; and Camp Bragg, Fayetteville, N. C. Traveling by train, it would have taken the Chief of Air Service several days longer to cover the activities which he inspected.

General Patrick, accompanied by Major H. A. Dargue, left Washington on May 19th, and proceeded by train to Miami, Fla., where they inspected Chapman Field. They were shown about Miami and Miami Beach by the President of the Chamber of Commerce of Miami. On Sunday, General Patrick, piloted by Major Dargue, made a 175-mile trip across the Everglades by way of Lake Ocochobie to Carlstrom Field in a JN-6 training plane. After inspecting Carlstrom and Dorr Fields they flew to Jacksonville, Fla., approximately 250 miles distant, in four hours flying time. They landed at Sanford, Fla., for gas and oil, and proceeded by way of Daytonia and St. Augustine, flying about 150 feet above the beach and inspecting the beautiful scenery and resorts along the same. At Jacksonville they were met by two DH-4's which had been sent down from Montgomery, Ala.

On Wednesday, May 24th, General Patrick and Major Dargue flew to Americus, Ga., a distance of approximately 210 miles, in two hours flying time. After inspecting Americus, both the depot and the field, they flew over to Camp Benning, Ga., a distance of 50 miles, and attended the Barbecue incident to the graduation of the class from the Infantry School at that station. They left Camp Benning shortly after lunch and flew to Montgomery, Ala. This trip required 1 hour and 10 minutes, and they passed through several rain storms on the way. The next morning, the 25th, they left Montgomery at 7 o'clock and made a non-stop flight of 6 hours and 25 minutes to Camp Bragg. Fayetteville, N. C., the distance being 525 miles.

After inspecting the Air Service activities at Camp Bragg, they completed the trip to Washington in little less than 3 hours, a distance of 280 miles.

Training Schedule for 23rd Balloon Company

The 23rd Balloon Company, stationed at Post Field, Fort Sill, Oklahoma, started on a training schedule on May 1st, and the following military and technical subjects will be covered by July 1st: Field Service Regulations, Manual of Interior Guard Duty, Infantry Drill Regulations, Telephones, Windlass, Balloons, Machine Guns.

Activities of the 22nd Squadron (Observation)

An official report covering the operations of the 22nd Squadron (Observation) stationed at the Air Intermediate Depot at Montgomery, Alabama, during a period of six months from November 4, 1921 to May 4, 1922, shows that excellent progress has been made. Among the various achievements of this squadron during the above period, particular mention may be made of the fact that a total of 1364 flights were made for a total duration of 448.20 hours, with but one wreck, this being a plane returning from a cross country trip from Birmingham, Ala., which was forced down through inclement weather in a poor landing field. In landing the plane turned turtle, damaging the propeller, wing surface and rudder, no injuries resulting to either pilot or passenger. The plane was subsequently repaired and flown to its home station.

A summary of the work of this squadron is as follows:

	Flights.	Hours
Cross Country	230	220,20
Target and Practice Flights	781	117.15
Formation Flights	13	10.5
Infantry Contact	60	34.20
Communication Flights	80	22
Photographic and Reconnaissance	184	35.55
Bombing	16	8.25
Total aircraft flying time		448.20
Total number of man hours		837.35
Total number of man miles		40,904

During this period the squadron has successfully handled seventeen Infantry contact missions with the Infantry School at Camp Benning, Ga. These missions have required from one to seven planes. To successfully work with the Infantry School, it has been necessary, in a great many instances, to require the pilots and observers to remain overnight at Camp Benning. Twelve lectures have been given the Field Officers' Class, Company Commanders' Class, and Basic Class of the Infantry School at Camp Benning during the present course. Members of these classes who so desired were given a reconnaissance flight over the Camp Benning reservation. This was the first opportunity many of these officers ever had of taking advantage of an aerial flight. Fifty-five members of the Field Officers' Class, seventy-nine of the Company Commanders' Class and forty-six of the Basic Class were given reconnaissance flights, making a total of 180 students at Camp Benning. Ga., who took advantage of this opportunity.

During the last two weeks of February, two officers and ten enlisted men of the Communication Detail, 29th Infantry, Camp Benning, Ga., were ordered on temporary duty to the Montgomery Air Intermediate Depot, where they were given a course of training by the Radio Department of this Squadron in aerial communication. Numerous test flights and special tests, as outlined by the Experimental Department of the Infantry School, were conducted. This training proved of mutual benefit to the two arms, and the officers and enlisted men, completing the course, expressed themselves as being well pleased with the training received.

Eleven recruits were carried by airplane from Montgomery to their permanent assignments at Camp Benning. The flights accomplished were featured by the recruiting officers both of Montgomery and Camp Benning. Local articles were inserted in newspapers throughout the Corps Area as a means of stimulating recruiting for the Infantry School.

The strength of the squadron is 10 officers (8 pilots and 2 observers) and 90 enlisted men. The flying training shown above is in addition to the aerial observation training and military subjects covered during this period by both the commissioned and enlisted personnel in post and unit schools.

Bombing flights have but recently been started, due to the fact that no ground is available at this depot for this training. Arrangements were recently made with the Infantry School, Camp Benning, Ga., whereby the squadron will use one of their many target ranges for this training. This will necessitate an hour's flight from the airdrome to the bombing range.

Conversion of a JN-6H Aeroplane into Ambulance Aeroplane

The Engineering Department at the Fairfield Air Intermediate Depot, Fairfield, Ohio, has completed the conversion of a JN-6H airplane into an Ambulance Airplane. In making this conversion no prints or data were available which were of any benefit in making up a set of prints by which the conversion could be made. Through the efforts of Mr. Herbert D. Penney, of the Drafting Department at the Depot, a drawing and set of prints were made of the proposed airplane and submitted to the Engineering Division at McCook Field, Dayton, Ohio and approved.

The take off is unusually long, due to the excess weight, but the ship handles well in the air, though not as sensitive to the controls as the standard type. The unusual feature of this type of Ambulance Airplane is the location of the physician and the litter. By means of a window, the physician can observe the patient at all times. The litter is easily accessible and can be removed from either side of the fuselage. A special compartment constructed in the fuselage takes care of the first aid kit, instruments or medicines.

The plane is equipped with a standard 31-gallon capacity tank, with an approximate flying radius of two hundred miles. It has a flying speed of from fifty to sixty-five miles per hour, and a landing speed of from thirty to forty-five miles per hour, depending upon the load. As no altitude flight has been made, its maximum altitude cannot be given at this time.

FOREIGN NEWS

British Aviation

New regulations for securing greater safety on the Paris-London Air route have heen accepted at a meeting of French and British pilots. They agreed to the outward and inward routes being separated by a distance of approximately 10 kilometers (6¼ miles). This arrangement will add slightly to the mileage of the route from London to Paris and necessitates some change in the ground arrangements, including the provision of supplementary landing grounds for cases of emergency. The line from Paris to London will be via Beauvais, Calais, and Dover, while the return journey will he hy Folkestone and Boulogne and then well to the right of the small hills at Cambres and Beauvais.

On Monday, May 7th, the first of the DH-34 machines helonging to the Instone Air Line made the inaugural flight from London to Brussels and back. The actual regular service is scheduled to start on May 15th, and the London-Brussels line may well prove in the future one of the most important radiating from London, linking up England with northern and central Europe.

One of the regular pastimes now for pilots flying between London and Paris on the British machines equipped with wireless is to ring one another up and have a chat in the air.

On Saturday, May 6th, further tests, this time successful, were carried out with the new parachute which is designed to lift a pilot out of a machine falling out of control. This time the tests were made with a triple paracbute, a very small one heing first released, which pulls out a slightly larger one which, in turn, exerts sufficient pull to release the large man-carrying parachute that finally lifts the pilot out of his seat. An ordinary parachute descent was also made.

Two Fokker monoplanes of the F3 type, hut fitted with Rolls-Royce 360 h.p. engines instead of 240 h.p. Pumas, are to be put on the London-Amsterdam service. These machines while retaining the same passenger capacity (five) will have another compartment added for goods and luggage. They are intended to do the double trip in one day.

German Aviation

The Konigsherg-Moscow air service on which Fokker monoplanes are used, was inaugurated on May 1st. At first the service will be bi-weekly, the machines leaving Konigsherg at 9 a. m., arriving at Smolensk at 4:15 p. m., leaving Smolensk at 4:45 p. m., and arriving at Moscow at 7:45 p. m. In the opposite direction the times are as follows: Moscow 6:30 a. m., Smolensk 9:30, leave Smolensk 10, arrive Konigsberg 3:15 p. m. Machines will leave Konigsherg on Sundays and Thursdays and Moscow on Sundays and Wednesdays. The railway journey between Berlin and Konigsherg occupies 12½ hours, and the flight between Konigsberg and Moscow 9 hours, giving a total of 22 hours, as compared with more than five days hy train. The air mail fees are to he 8 marks for post cards and 8 marks for every 20 grammes in case of letters.

The prohihition of German aeronautical enterprise, enforced hy the Entente during 1921, was scheduled to be lifted on May 5. Although the number of aeroplanes in use was negligible during the past year, seven German companies claim to have covered a total of 1,653,053 kilometers during the seven months from April to November, 1921, carrying 6,183 passengers and 30,713,428 kilos of post and parcels. (Commercial Attache C. E. Herring, Berlin.)

Traffic at Bourget

The traffic of the Bourget Aero Station (near Paris) is increasing considerahly, according to La Journee Industrielle of April 9-10. In March, 1922, there were recorded 315 airplanes, carrying 846 passengers and 21,908 kilos of merchandise. The corresponding figures for March, 1921, were 250 aeroplanes with 681 passengers and 8,725 kilos of merchandise.

Belgian Service

The "Sneta," a Government-suhsidised aerial transportation company in Belgium, has finished its trial period of passenger, merchandise, and postal aerial transport service between Brussels and cities in neighboring countries (Paris, London, Amsterdam, The Hague.) Belgian participation on these lines will, therefore, cease from June 1, 1922, leaving the Pais-Brussels and Blussels-Amsterdam services in the hands of French and Dutch companies. A Brussels-London service will he organized hy an English company, beginning in May of the present year.

The Belgian Government studying the creation of a permanent organization which will permit that country to conserve an important position in international aerial transportation.

. Dresden-Berlin-Hamburg

Beginning April 1, a daily passenger, mail and freight air service was re-estahlished on the line Dresden-Berlin-Hamburg and return; also on the line Dresden-Leipaig-Magdehurg-Hanover-Bremen and return. The trip from Bremen to Hamburg takes four and one-half hours, including a half-hour stop in Berlin. The journey to Bremen requires five hours, including 15 minute stops at Leipzig, Magdeburg, and Hanover.

The fare from Dresden to Berlin is 500 marks and from Berlin to Hamhurg 650 marks. This compares with 285 marks and 387 marks, respectively, for the first-class railway fare between the same points. Passage from Dresden to Leipzig is 500 marks and from Leipzig to Bremen 1,300 marks, as compared with 190 marks and 536 marks, respectively, for first-class railway fares hetween these points. Fifteen kiloa of haggage is carried without charge, and all excess at the rate of 15 marks per kilo.—*Commerce Reports.*

Calthrop Parachute Teata at Croydon

Some interesting experiments were carried out at Croydon recently with "Guardian Angel" parachutes. Unfortunately time did not permit of the carrying out of the full programme of the tests, hut further tests are to he made later.

The first drop made was of a dummy man with the "H" type "Guardian Angel" parachute with standard 28-ft. silk body. The dummy man was carried in the new frontal-suspension harness, fitted with instant connector and quick release, the life-line attaching the dummy man to this parachnte being fitted with a small resistance parachute to show the advantage of providing additional resistance to speed up the disconnection of a "dropping" type parschnte in a nose dive.

The test showed that the small resistance parachnte, which was only 4 ft. in diameter, perceptibly speeded up the extraction of the parachute and pulled the dummy man considerahly to the rear of the normal path nsually taken.

In order to avoid any possibility of accident to a pilot or acroplane, it is always preferable to test a new invention of this kind by a series of small advances without accident than to risk damage to the pilot and his machine hy making too hig advances at a time.

Although the reaistance parachute opened instantly, Capt. Muir reported that no shock whatever was felt on his machine, so that on the next occasion it will be safe to employ a resistance parachute of much greater area, in which the effect would be much more marked.

In the second flight the dummy man was dropped with an "H" type parachute, fitted with a newly-invented "Calthrop" hody, provided with three annnlar rings of air pockets, the object of which is to produce enhanced cantilever effect of the compressed air passing under the periphery of the body, and thus giving additional resistance. Again, in order to proceed without them for the sake of safety to the pilot and the machine, the air pockets were contracted to about one-tenth of their full extension.

The opening of the body was extranrdinarily quick, but perfectly elastic; and again Capt. Muir reported that there was no shock whatever to his machine. The resnlt of the experiment was to show that the rate of descent was appreciahly slower.

Aviators to Fly to Picnic

The first aerial picnic on record will take place in Paris, when thirty-five aeroplanes, hearing most of the famous pilots of France and the present and former Air Ministers and their wives, will take off from the Buc, Villa Couhlay, Issy-les-Moulineaux and Tonssus-le-Noble acrodromes for a landing field at Tillieres, sixty miles from Paris. Here a luncheon will be served from baskets hrought on the planes.

Capt. Rene Fonck, with Under Secretary of Aviation Eynac as passenger; Adjntant Jean Casale, with Senator Flandin, former Aeronautic Secretary, and Mme. Flandin aboard, and Sub-Lieut. Charles Nungesser, carrying Count de la Vaulx, will form part of the group. Other aviators who will make the trip are Lieut. Bossoutrot and Sadi Lecointe.

The London Aerial Derby

The *New York Herald* correspondent states that the air will he "lashed into a frenzy" at Hendon when the aerial pageant takes place there June 24. Unbeard-of stunts have been planned and the speed laws of aviation will be hroken. The mystery planes belonging to the Air Ministry will take part and give the puhlic the first opportunity to see these new planes designed to operate in conjunction with the hattleship fleet. These amphihians are made for channel traffic as well, and as soon as an aerodrome on the Thames is erected they will also be seen there.

The most striking feature of the program will he massed aerial attack on an improvised desert stronghold. No detail has been spared to make the structure realistic. There are palm trees, loopholed minarets and lookout towers that rise to a height of 100 feet from within a high walled fortress equipped with guns. The defenders will wear Eastern costumes.

For fifteen minutes a hattle will rage between an armed squadron of bomhing planes and the defenders. Later Lieut. W. H. Longton will give an exhibition of "frenzied flying" and stunts near the ground.

Rumania Accuses Reds of Propaganda by Air

Formal protest has been sent to the Russian conference at The Hague hy the Rumanian government, which declares Soviet Russia has violated the non-aggression pact hy sending propaganda into Rumania by aeroplane. The government has made specific complaint relative to the recent capture of a Bolshevik machine and its crew near Tichina.

The New Russian-German Air Linas

On May 1st a most important development in air transportation was inaugurated hy the opening of a direct and regular service between Konigsherg in Eastern Germany and Moscow. During the coming months the line is to he extended to Berlin and the service will become a daily one in both directions. The importance of this development lies in the fact that the line is one of the very few, perhaps the only one, which is an undoubted economic necessity, all previously existing means of communication hetween Russia and Germany being in a state of chaos through the war and its aftermath.

At the present time it takes about 5 days, and a considerahle amount of persistence, to travel between the two capitals. The mail takes an average of eight days and even telegrams four days in transmission. The section already in operation, Konigsberg-Moscow, a distance of 780 miles, is flown during the day, in two stages of four hours each. The airline shortens the trip to 30 hours.

For the present, the entire passenger and mail space has been reserved hy the German and Russian Governments for the use of couriers and the carriage of official correspondence and documents.

Although operated hy a German company, hacked hy several of the greatest German industrial and shipping interests, the planes used are made in Holland and the motors are English. Ten Fokker F 3 monoplanes of the latest type were huilt at the Netherlands Aircraft Mfg. Co.'s plant at Veere, Holland, and successfully delivered hy air. They are fitted with 340 h.p. Rolls Royce motors and develop a speed of 115 miles per hour. The cabin arrangements are even more complete than in the 3 machines which are so well known in this country. A large haggage compartment has been added behind the cahin, and for the use of the couriers 3 sleeping berths are provided, which can instantly be converted to seats for 6 persons for use in ordinary day time traffic. A very effective arrangement for heating the cahin with clean, warm air is also installed.

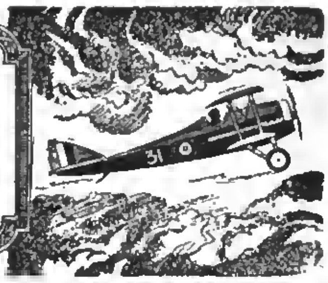
ELEMENTARY AERONAUTICS *and* MODEL NOTES



Details of Illinois Model Aero Club Models

(*Continued from Last Week's Issue*).

Bending Bamboo

A few simple rules will help an amateur to bend bamboo. First, use *good* bamboo; not old dry rotten stuff; scrape the hard outside off as well as the soft inside and hold it near the flame, either to one side or above, and move the piece back and forth until it commences to bend. A, can be made much longer than B. and still not warp easily. If it does commence to warp it can be straightened easily. The cross-piece in A keeps the top-piece from sagging under the pull of the doped paper.

Adjustable Wing Clips for Scale Models

These clips make it easier to adjust the wings. Wire hooks C-C with two loops are fastened over the wing LD. Aluminum strips A-A bent double are fastened to wing struts B-B and then drilled twice as shown. Similar attachments to the rear complete the unit. With this arrangement the wing can be moved backward or forward and also be warped.

Double Surfaced Wings

Double surfaced wings are more efficient than single surface but are much harder to construct. A is the beam which, if pine, should be close to 1-32 inch thick. The height of the beam depends upon on the wing section chosen by the builder. E are the ribs, which are formed as close as possible to the section copied. Ribs should be made 1-64-inch sq. to 1-32-inch sq., according to the size of the wing, if the material is of bamboo. If the ribs are of balsam 1-16 inch, they should be about strong enough and can be hollowed out like the ribs of a large machine to make them lighter. Two bamboo pieces, B, fastened to the end of the wing-beam enable it to stand any shocks it receives in landing. If the brittle white pine were extended to the end of the wing it would very likely snap off the first time the tip received a severe shock. C, is the wing tip which should be bound as shown to the wing beam D, at the point F. Entering edge D is fastened to the ribs E as shown directly above the drawing of the wing tips. An expert with Ambroid can do this operation without binding. Entering edges 1-32 in. in diameter will stand the pull of a lightly doped wing with ribs about 2¼ inches apart. The paper can be stuck on the frame with either Le Page's glue or banana oil, and the surplus paper around the edges cut off with a sharp razor blade. Either one or two wing beams can be used in a double cover wing.

Scale Model Nose No. 2

This model nose is familiar to I. M. A. C. members. To the nose C is attached the block H, to hold the motor-base in place, by means of the wire spring E, which is looped under pins D, which are inserted in the nose. The dress snaps A are fastened to the balsa nose C by wire, thread, and glue. The other half of the dress snaps are lined up on the body in the proper place.

Scale Model Nose No. 1

Model Nose No. 1 is the same type that is used on the S. E. 5 scale model which was built by Mr. Jaros and flew so well. A is the balsa nose into which are inserted the wires E with snap style of end which does not pull out of the tube T easily. This can be made of aluminum sheet rolled if no other is suitable. To the nose A is also permanently fastened the two bamboo strips C, on each side of the hole for the motor-base. The motor-base is thus detachable. To the motor-base B is fastened the cross-piece D. The front of the nose is rounded to cut down resistance.

Wheels

Balsa wheels present a realistic appearance and are not so hard to make if one has an electric motor around the house. The rim is turned out of balsa by using sandpaper as a tool. Then the stiff paper sides C and D are glued in as shown. Side D is one thickness of the stiff paper made into the form of a cone by cutting out a pie-shaped piece and gluing the edges together. The washer E is then glued securely to the centre to be the bearing of the wheel. Another similar piece of paper is glued over the first to make two thicknesses for strength and this is followed by another washer. The hole at the center should be large enough to permit a large diameter pin to pass through and form the axle.

The paper wheel is easier to make. It is built up of two sides formed of the familiar cones which are glued together at the edges. Washers are glued inside at the center to form the bearing. They should be spun on an axle and trued before the glue sets.

The balsa and paper wheels are suitable for scale models. The small paper wheels are suitable for R. O. G. twin pushers but the small cork ones are better yet. A piece of balsa could be used in place of the cork piece B. Washer bearings are used as in the other wheels. D are the supports to which the axles are attached for use in twin-push R. O. G. machines.

The Preservation of Model Rubber

The rubber strands used for motive power on model aeroplanes is kept in good condition longer by keeping it well covered with soapstone when not in use. The rubber should be powdered after every five or six flights with graphite, soapstone, or a mixture of both. Graphite is the best but is dirty to handle. In making up the motors for a model it is necessary to make a joint in the rubber. The best way to do this is to tie a squore knot in the rubber and roll it until it is securely tight. In keeping rubber, light should not be permitted to reach it and oil should be kept from it, for they will injure rubber.

The Illinois Model Aero Club

Mr. M. L. Bramberg, chairman of the Contest Committee of the Illinois Model Aero Club announces that his club is trying to get up a National contest for model aeroplanes during the Pageant of Progress to be held in Chicago from July 29th to August 14th.

It is their desire to offer cash prizes and trophies for different kinds of contests and to secure the co-operation of all other model aero clubs throughout the country.

Letters have been written to all the model clubs, but few have replied. Mr. Bramberg says the boys of the I. M. A. C. are beginning to believe they are the only ones in this country who can build record models and in order to find out if this is a fact or not, it will be necessary to establish a contest of this kind. The other model clubs should take up the challenge and a lively contest is sure to result.

The Illinois Model Aero Club has its headquarters at 430 South Michigan Avenue, a club room on the Parlor Floor of the Auditorium Hotel (care of the Aero Club of Illinois—phone Harrison 3289) and the flying field is at Cicero Avenue and 83rd Street, Chicago, Ill.

World's Records of Model Aeroplanes

Tractors

Type of Contest	Record	Record Holder
Rise-off-ground, Duration	227.4 seconds	Breckenridge
Rise-off-ground, Distance	2685 feet	Breckenridge
Hand-launched, Duration	240 seconds	Lathrop
Hand-launched, Distance	2465 feet	Pond
Rise-off-water, Duration	116 seconds	Hittle

Twin Pushers

Type of Contest	Record	Record Holder
Rise-off-ground, Duration	170 seconds	Lauder (N.Y.C.)
Rise-off-ground, Distance	4029 feet	Schweitzer
Hand-launched, Duration	230.8 seconds	Schweitzer
Hand-launched, Distance	5337 feet	Hall
Rise-off-water, Duration	118 seconds	Likosiak

RADIO DIGEST

Control Aeroplane Flight by Wireless in France

In addition to controlling the flight of an aeroplane by radio, attempts are being made in France to devise mechanism to enable a plane not only to ascend pilotless, but also to land without any hand on the controls.

Devices in course of perfection show wonderful ingenuity. In one case, a machine without a pilot, its engine having been started, runs across the aerodrome, causing to revolve at a rapidly increasing pace a small two-bladed fan or screw between the wings. The fan, as soon as it turns a certain number of revolutions, actuates mechanism which places the control surface of the machine in the right position for ascent, its maneuvers while aloft being controlled by wireless.

When the time comes for landing a signal has the effect of unrolling beneath the aeroplane a length of wire with a weight at the end. This weight, touching ground while the machine is at some little height, switches off the engine and causes the rear surfaces of the plane to set themselves in such a position that the landing wheels of the machine make a smooth contact with the ground.

French radio control of aeroplanes has achieved already a notable triumph. A large machine was taken up by its pilot, who left the controls and allowed the machine to be maneuvered for more than an hour by wireless operators in a land station far below. At a given signal the pilot resumed control and landed.

Radio Success Depends on Details

Attention to details which seem unimportant has made it possible for many a home-made radio set in the hands of a careful operator to establish a long-distance record or clearness of signals far superior to the attainments of an elaborate outlay of instruments under the operation of a careless operator. In radio receiving a feeble electrical current is being dealt with, and the little things which seem almost insignificant count to a great extent in successfully developing a weak signal to audibility and a loud signal to marked intensity.

A straight copper wire, size No. 14, about 100 feet long, serves as an excellent antenna for receiving radio broadcast news or music. The outside antenna is subjected to the elements of the weather, and it also is in a position to swing about in the wind. All aerial connections should be soldered firmly, thus affording good electrical connections and keeping joints free of dirt, which is likely to serve as insulation. If antenna connections are not soldered the result is certain to be loose connections when the wind blows. The antenna should be well insulated and free from all objects. Otherwise, especially in damp weather, much of the energy, if not all, will find its way to the ground before reaching the receiving instruments. The antenna wire can be either bare or covered with insulation. It is important to connect the ends of the wire to insulators instead of direct to the spreaders or poles, because wood when wet is a good conductor of electricity. The guy wires also should be broken up by an insulator. Never erect the antenna parallel to telephone or electric light wires, as interference by induction generally results. In many instances where radio wires have paralleled a telephone line the regular phone conversation has been heard in the wireless receivers.

The ground connection should be soldered or clamped securely, instead of carelessly wound around a pipe or rod which leads to the earth. Before the connection is made the pipe or surface to be connected should be thoroughly scraped and cleaned. A faulty ground connection has hindered many a fine radio set from producing clear signals. A copper boiler or sheet buried several feet in the earth serves as an ideal radio ground because it has considerable area. Surround the copper surface with charcoal and sand, as such a combination tends to hold moisture around the metal, making it a more efficient ground.

The next best ground and easily within the reach of all is the cold water pipe. The next selection is the radiator, and then the gas pipe. Architects, when planning a home, may soon provide for a radio ground connection. A sheet of copper could be buried underneath the cellar floor and the connection extended to the baseboard sockets in the music room, living room or any room in the house where a radio set might be used.

All connections in a radio hook-up should be soldered whenever possibie. By constant turning of the knobs and dials the wire in time will work loose and trouble result. Sliding contacts and switch points always should be kept clean, as dust and grease are sure to accumulate and serve to insulate the electrical connection. It will be surprising how neatness, cleanliness and attention to details in radio work make possible increased range and intensity.

Efficiency of Indoor Aerials

The greatest mystery of radio, in the minds of many people, is that the signals can be intercepted by an aerial inside a building without even a window being open. The results with an indoor antenna are not as satisfactory as when the antenna is in the open. Nevertheless, with a step or two of amplification remarkably clear, signals may be heard by the use of an indoor antenna. A wire extended down the hallway and hidden behind the molding will give astonishing results.

Little do we realize as we sit in our homes reading the papers that the latest news of the world is passed before us—in fact, right through our bodies—at the speed of 186,000 miles a second. Every minute of the day and night invisible radio waves rush through our homes and offices, carrying the melodious strains of bands and orchestras; the voice of a speaker far away, or the dot and dash of a ship in mid-ocean. The messages of the world are ever present just like the medium which transports them —the ether.

Ether is an invisible, odorless, tasteless substance found everywhere from the most perfect vacuum to the highest and greatest mountains. Therefore, anything traveling with such a substance as its medium of transportation goes through everything and thus radio travels unseen, showing no preference, through the millions of homes in the world. A little receiving set connected to a wire inside the house will prove that there is more truth than poetry in the lines of the old song, "There's Music in the Air."

Radio Wave Lengths

The distance a radio wave travels does not depend upon the length of the wave, as many people think. The power of the transmitter and the sensitiveness of the receiving apparatus govern to a great degree the distance the signals may be heard, and atmospheric conditions also play a part. A short wave may travel thousands of miles, but it is not capable of carrying high power and, therefore, the message carried on a low wave length weakens as it gets further from its origin.

A wave length is the distance from one point in a wave to the next point in a like phase; in other words, the distance from crest to crest. Long wave lengths are used for long distance work because low frequency currents carry far better than high frequency currents, which make up the shorter waves. Wave lengths are measured in meters, a meter being 39.37 inches. When the instruments are tuned to receive a certain wave length they merely pick up sounds of a definite number of vibrations. Enemy submarines during the war used as low as 75 meters for transmission, and the powerful station at Nauen, Germany, used a wave of 12,600 meters.

The Lafayette station near Bordeaux, France, uses the longest wave of any radio station in the world at the present time. It is 23,000 meters, about fourteen miles in length. Second place belongs to Long Island Central—19,000 meters. This is approximately twelve miles from crest to crest for a wave leaving the Long Island station. The distance a message travels from Long Island to Germany is about 4,000 miles. Thus, there are a trifle more than 333 complete dips or troughs in the distance between Long Island Central's antenna and Germany's wires. Arlington, Va., sends time signals on a 2,500-meter wave. Radio telephone broadcasting from WJZ, Newark, and the majority of other broadcasting stations, is on 360 meters.

Care of the Storage Battery

A storage battery might be termed the heart of a radio receiving circuit when the vacuum tube is used in place of the crystal detector, as it renders the life-giving current to the hook-up, which is merely the veins and arteries of the receiving set.

The storage battery—or, as it is called in radio, the "A" battery—must receive a certain amount of care and attention if it is to produce efficiently over a reasonable period of years. The development of radio equipment during the last year or two has made it possible for operators of audion sets to charge their own batteries, and it must be remembered that violent discharging and excess overcharging shortens the life of the cells, causing injury to the plates by warping or buckling.

Distilled water should be added to a battery at least every two weeks. The electrolyte, which is a definite mixture of chemically pure sulphuric acid and pure water, should not be permitted to fall below the tops of the plates. Exposure of the plate tops induces sulphation, a chalky deposit, which is a non-conductor of electricity, thus causing internal resistance. During the summer months it is well to add water once a week, as evaporation is more rapid in warm weather. Care must be taken not to raise the electrolyte level too high above the plates, as the solution is apt to slop over

Digitized by Google

and cause a short circuit on the exterior of the battery. The electrolyte also will eat the case and sulphate the terminals. This may be prevented by wiping off the terminals with a vaseline-covered rag. It is a good rule to keep the electrolyte level about one-quarter of an inch above the top of the plates, and always keep the top of the battery case dry and clean.

Idleness is bad for batteries, so if the reader goes away during the summer months the radio storage battery should be left in the care of a battery service station and charged at least once a month during periods of idleness.

It is always well to have a syringe-hydrometer as part of a radio equipment. Such an instrument indicates the condition of the storage cells. The power of a storage battery gradually diminishes as it is used, but after a certain point of discharge is reached it weakens quickly, without any advance notice, and in such a condition is of little service to the audion. Therefore, it is well to test the specific gravity of the cells from time to time. A musical concert may hold special interest some night, and it is aggravating to have a battery weaken on an occasion when its best performance is needed.

To test the specific gravity of a cell, remove the vent, insert the tube at the bottom of the hydrometer syringe into the electrolyte. Squeeze the rubber bulb, then remove the pressure from the bulb. Electrolyte will rise in the glass barrel. Read the figure reached by the surface of the electrolyte. The figure 1.285 is the "full charge" for battery specific gravity. The figure 1.270 indicates one-quarter discharged. The reading 1.255 shows that the battery is half discharged. At 1.225 the battery should be charged.

After the reading is noted, squeeze the bulb to expel the liquid from the tube and always restore the electrolyte to the cell from which it was taken—never to another. Always take the hydrometer reading either before adding water or after there has been an hour or two of use to insure thorough mixing. Water mixes slowly with the electrolyte since the acid is the heavier.

The Buzzer Test

In using a crystal receiving set the first operation is to adjust the detector; that is, find a sensitive spot on the mineral, generally a piece of galena. All crystals have good and bad spots and therefore a fine wire which makes contact with the surface of the galena must be moved about until a sensitive spot is located. After the select spot is discovered the detector is all set to perform by permitting the passage of the feeble high-frequency wireless currents through the phones and causing the diaphragm to vibrate, producing a sound audible to the ear of the operator.

When an operator opens the crystal set for "listening in" he must adjust his crystal by the music or signals passing through the air, and by doing this a part of the concert is lost. A buzzer test serves to have the apparatus adjusted to its maximum degree of sensibility when the broadcasting concert begins. An operator might sit for hours "listening in" with the idea that the crystal detector was finely adjusted and still have the contact wire off the sensitive spots. When a buzzer test is used the operator can press the button or close the switch which completes the buzzer circuit at any time and thus be assured that the set is perfectly adjusted. The buzzer merely sets up vibrations in the receiving set which are used as a substitute for radio signals.

Getting Results from Home Radio

Radio receiving has passed the experimental stage and reached the point where it is a source of amusement, pleasure and instruction to the average person. As a matter of fact, the majority still regard radio as a means of receiving, rather than transmitting.

Roughly speaking, there are three types of receiving sets today, each with many modifications and varieties. The best known and least expensive is termed the Crystal Set. Many amateurs have constructed their own sets of this type, or they can be purchased complete. The radius of operation and efficiency is limited, ordinarily, to within twenty-five to fifty miles of the broadcasting stations, and requires the use of head-sets, without permitting the use of a loud speaker.

The next set is called the Audion or Vacuum Tube, with a range up to 500 miles if only one detector and one amplifier be used. By increasing the number of tubes the radius can be extended to a thousand miles or more.

The third type embraces the vacuum tube, the cabinet also containing a regulation phonograph equipment, whereby the one instrument, at the will of the owner, can be used for the receiving of wireless messages or the playing of phonograph records.

Knowledge

"Listening in" is far more enjoyable and much better results can be attained when the sets are understood in greater detail, and how and why the various instruments are used, rather than by "just turning a knob or a dial."

Function

The function of a receiving set is to absorb the energy from the passing electromagnetic waves sent out by the broadcasting stations in the form of what is technically termed radio frequency oscillations, and then to transform this energy into audible sounds, be it music, speeches, or what not; in other words, to make it possible to hear clearly and distinctly.

Construction

The principal parts of a receiving set include the antenna, or aerial, which is a copper wire that intercepts or catches sound waves. Satisfactory results require at least one hundred feet of wire. With the improvements in amplification, it is now possible to use indoor aerials with splendid results. It is said that a well-grounded aerial will protect a whole city block from being struck by lightning.

The antenna transfer switch, which serves to connect the aerial with the set itself, is another important unit, and telephone receivers, commonly called head-sets, are essential. Radio phones are said to be of high frequency because of the great length of fine wire used in their coils, but, as this wire is always the finest copper, the resistance of a good phone may be as low as 2,000 or 1,500 ohms. The ohm is the unit of resistance. As a matter of comparison, the average telephone receiver is less than 100 ohms. The cross-sectional area of the radio phone is low; therefore, higher resistance is not wanted, but cannot be avoided. A few turns of German silver wire would produce 2,000 ohms resistance, but no magnetizing effect.

Radio phones have permanent magnets to keep the diaphragm under a constant strain, to prevent hysteresis (heat) losses. They will not operate on oscillating current, because the inductive reactance is too great and the current cannot pass through the phone. Even if the current could pass, the diaphragm could not vibrate so fast, and if the diaphragm could vibrate at that speed the human ear would be unable to hear it.

The loading coil, which makes it possible to increase the wave length of the set, thereby enabling the user to hear a greater number of stations.

The receiving transformer is designed to transfer the weak oscillations of extremely high frequency from one circuit to another. In the words of the layman, this merely means a finer tuning, eliminating interference of other stations.

The detector apparently is the most important part of the set to the average person. It rectifies the incoming oscillations of the wave train into direct pulsating currents, thus enabling operation of the phones at audible frequency.

The broadcasting stations transmit sound waves, termed radio frequency, at a rate as high as 100,000 oscillations a second, but the human ear cannot hear in excess of about 1,000 a second. Therefore, the detector actually transfers the waves from radio frequency into audible frequency.

When the condenser, which controls wave lengths, is put in series with the ground it tends to shorten the wave length. Placed in parallel to the open circuit, it permits the reception of longer waves. Placed parallel to the closed circuit, it is used to bring the secondary into resonance with the primary. Placed across the phone, it stores up the rectified oscillations and then discharges them through the phone with cumulative effect.

The buzzer circuit, which enables the operator to adjust his detector in advance to the maximum degree of sensibility, gives assurance that a calling station can be heard.

The safety or micrometer gap is connected across the aerial and ground terminal to prevent static discharges or strong near-by signals from throwing the detector out of operation.

The amateur, to increase his knowledge and obtain the best results, should study radio in the following order: Construction, arrangement, operation, function, care and principle of operation.

Detector

The crystal detector is mentioned so often that it is worthy of description. Galena is the most used mineral and is the best for the reception of weak signals. It is the most suitable for the set of short range. Carborundum as a detector is very stable and not affected by strong currents, but fails to be a good rectifier. Silicon is not as sensitive as galena, but is a better rectifier than carborundum. A sharp point of antimony pressing on silicon gives good results, but is not as sensitive as galena and will not give as loud and clear signals.

Audions

The simple audion or vacuum tube circuit consists of five parts—the bulb, containing three elements; the filament, the grid or zig-zag wire, and the plate, which is solid metal; high voltage or B battery; low voltage or A battery: rheostat for control of the A battery voltage; condenser in series with the grid.

The primary advantages of the audion compared with the crystal is that it is more sensitive, is not so readily put out of adjustment, permits receiving from broadcasting stations at a much greater distance, and enables the use of a loud speaking horn, whereby sounds carry clearly in a large room and in auditoriums.

Coupling

Coupling is the method of transferring the energy absorbed by the aerial from the primary to secondary. It permits a finer tuning, thus preventing interference when two or more stations are broadcasting simultaneously on a similar wave length.

Close coupling results in a larger transfer of energy from the primary to the secondary, and the circuits need not be in resonance. It is used for "listening in," as many wave lengths can be heard without readjustment.

Digitized by Google

Loose coupling gives a smaller transfer of energy from the primary to the secondary circuits. With this type the circuits must be in exact resonance. It is used in tuning out or preventing interference, as only one station and one definite wave length can be heard well.

The primary circuit is used for the original or crude tuning, which is transferred by mutual induction to the secondary circuit, which in turn gives the finer tuning.

When the broadcasting station and the receiving set have the same wave length they are said to be in tune or in resonance. Where the wave length is different, naturally there must be an adjustment on the part of the receiving set.

The characteristics which determine the efficiency of the receiving set are: Range—detector and phone; audibility—condenser; selectivity—coupling.

To tune a receiving set to a distant broadcasting station it is necessary to adjust detector to its maximum degree of sensibility by means of the buzzer circuit. Set the secondary to approximately the desired wave length, using large values of inductance and small values of capacity. Increase or loosen the coupling. Add or subtract inductance and capacity in the primary circuit until response is heard in the phone. Loosen the coupling until interference is eliminated or reduced to a minimum. Try new values in both circuits until the loudest sounds are heard with a minimum of static and interference.

If the secondary circuit is calibrated, it can be set at once to the desired wave length. The primary is not calibrated, due to the fact that no two aerials have the same wave length. After installing a set to a certain aerial, the operator can make proper calibrations on the primary.

Field Locater Makes Travel by Air Safe

Radio and flying are inseparable. This vital fact is becoming more and more evident to those engaged in the development of commercial aviation. Radio has already removed the terrors of fog from aerial navigation and has made night flying possible. Without night flying no system of civil aerial transport will ever be successful.

In a recent article on this page the work of the United States Air Mail Service was outlined. This service has done some remarkable pioneer work in the development of radio as an adjunct to aerial navigation, and of this work there is no question that the field localizer is the most important of all.

It is one thing to guide an aeroplane safely through a fog to the place where the pilot of the machine desires to go and quite another to bring the ship safely to earth. This fact was demonstrated in the transcontinental air race two years ago, when the big Martin bomber was caught in a fog between Des Moines and Omaha. Her pilot used all his skill and judgment in bringing the big machine to earth, but was unable to avert a crash. His skill reduced the seriousness of the forced landing, but did not prevent the subsequent crash.

Fog Chief Danger in Flying

There is no more embarrassing situation for the pilot of an aeroplane than to be in a dense fog at the end of his journey without fuel. It is impossible to remain in the air, and yet he does not know the nature of the ground below him. A crash under these circumstances is practically inevitable.

With this situation in mind, the engineers of the United States Air Mail Service started three years ago a series of experiments designed to eliminate this danger from the art of aerial navigation, and they naturally turned to radio as the means to achieve their object.

With the experience of the radio direction finder before them, they know that electro-magnetic waves could be sent out in one direction with certain types of transmitting equipment. Now, the logical inference was that if apparatus could be developed which would shoot a beam of electro-magnetic waves vertically into space, a pilot would be enabled to tell just when he was over the center of the landing field where he desired to alight. This is the basis of the radio field localizer, which was subsequently successfully developed.

System Not Perfected

The perfection of this apparatus did not, of course, come immediately. It followed a series of careful and persistent experiments, which at first were far from successful. The system, however, has now been perfected, and will soon be in general operation at all of the air mail flying fields, in accordance with the radio expansion program which the chiefs of the service are now engaged in promoting.

The official description of the apparatus is as follows: "The localizer is a device for transmitting radio signals more or less vertically, so as to form an electro-magnetic field over the landing field itself, and extending to a sufficient altitude to enable the pilot to intercept this zone of sound above the clouds or fog."

When the experiments were first started, efforts to achieve the end in view were made with a current of audio-frequency. Coming back to the official description, we are told: "This device consisted of a single turn of wire of fairly large diameter, with weather-proof insulation, which was laid around the outside of the flying field.

Audio-Frequency Used with Loop

"In actual experiment this turn—or loop—was 2,500 feet in diameter. It was found that when the output of a 500-cycle generator was supplied to this loop directly with key modulation, an electro-magnetic field was produced in the form of a cone whose area decreased with altitude. The uppermost effective limits of this device were around 3,000 feet."

For practical purposes this system was not successful, as a study of the results obtained will show. As described above, the electro-magnetic field above the loop aerial was in the form of a cone with the apex in the clouds. Now it will be readily seen that an aeroplane flying at normal altitudes would have extreme difficulty in passing through the zone of the electro-magnetic field, and it would be only the merest chance that he would happen to strike it. Machines flying at greater altitudes than 3,000 feet would not pass through the magnetic field at all.

There was another disadvantage to this system, and it lay in the fact that as the cone of the magnetic field was pointing upward, the width of the field was greatest at its base, which, of course, was on the ground. This meant that as the pilot came closer and closer to the ground the more uncertain he would be as to just where the center of the landing field was located.

An Inverted Cone Needed

From this it will be seen that what was needed was an electro-magnetic field in the shape of a cone; whose base was up in the clouds and its apex on the ground.

The next experiments designed to achieve this result were made with currents of radio-frequency. The device used to accomplish this result has been standardized and is the so-called "field localizer." Reverting back to the official description, we find the following:

"This device consists of two loops, each with a single turn, separated by a distance of about twelve feet, wound parallel to the earth's surface. A radio-frequency current is used, which flows through these coils in opposite directions.

"In actual practice these coils are wound around a wooden hangar, from which they are carefully insulated. As stated, a radio-frequency current is used in this device with key modulation. The resulting electro-magnetic field takes the form of a cone whose size increases with altitude, so that at a height of 3,000 or 4,000 feet the diameter of the cone is over half a mile."

It will be seen at once that this is the ideal situation, because the greatest area of the electro-magnetic field is where it is most needed—that is, at high altitudes.

Pilot Can Lay Straight Course

Now, the pilot caught in a fog can determine his exact location by means of his wireless compass, or radio direction finder, and he will then know how far away he is from his home field and what direction the field is bearing away from him. He can then lay a straight course for the field.

He then has to pass into the zone of the electro-magnetic field of the localizer, and with known current strengths he can pretty well estimate his altitude above the field, especially with the aid of his altimeter. The wonderful part of the inverted cone electro-magnetic field of the localizer is that it enables the pilot to spiral down slowly and gently along its outer edges until he can discern the outline of the landing field below him.

It has been found in the experimental and practical work with this device that the ordinary direction-finding apparatus installed on the aeroplane can be used successfully with the localizer. This is a very important thing, because it reduces the amount of apparatus necessary on the aeroplane and correspondingly keeps the duties of the pilot within reasonable limits.

The experiments with the audio-frequency currents which were first carried out made it necessary to install separate coils around the outer edges of the lower wings. This was unnecessary with the radio-frequency currents.

The field localizer and the radio direction-finder have eliminated the last preventable causes of danger to aerial navigation, and what is more important, they make night flying an actuality.

In connection with the immediate plans of the Air Mail Service, Colonel Paul Henderson, Second Assistant Postmaster-General, makes the following statement:

"We have come to the conclusion that the air mail has reached its limit operating only by day, because the railways afford a twenty-four-hour-a-day service. For several months we have been arranging for night flying. Two big tasks were to be done; one, equipping of all mail planes with radio; and second, establishment of aerial light-houses or electric beacons and flood lights at emergency and regular mail fields, at approximate distances of thirty to forty miles, all the way across the continent between New York and San Francisco. We are doing these things at present.

"Our fourteen main fields are equipped with radio stations, and we hope to have the first of the planes equipped with radio shortly. They will have wireless telephones and radio direction-finders. By using the direction-finder a pilot will be able to keep on his route in darkness, storm or fog, and the beacons at his objective will guide him directly over the field when the floodlights will be turned on, enabling him to land as easily as in daylight.

"We have already carried the mail from coast to coast in less than thirty hours, and we think we can provide steady service of this sort. It will be important, too. For example, mail leaving New York after the close of business will be delivered in Chicago before business starts next morning.

SEAPLANE, THREE SEATER, side by side Dep, OXX6, entire machine overhauled, new wings and wires, extra prop. Half interest $500.00 or sell outright $900.00. Address Airplane, 1207 Girard St., N. W., Washington, D. C.

BARGAIN—Anzani 10 cyl. aircooled 100 H. P. just tested. Full of pep. $140.00. Propellers for OXX6, new, $20.00. Engines for speed boats and small aeroplanes 45 to 60 H. P. cheap, all complete. William Yourwith, 21 Lasalle Court, New Britain, Conn.

EX-NAVAL AVIATOR—Desires position as pilot. Over twelve hundred hours flying time. Good record. References. Address Box 683, c/o Aerial Age Weekly, 5942 Grand Central Terminal, New York City.

FOR SALE—100 new Stone Supreme mahogany propellers, including Hissos, Liberty and brass tipped OX's $40.00 each. Deposit required. M. J. Stone, 800 South Fourth St., St. Louis, Mo.

FOR SALE—Aeroplane without motor, has never been assembled, $125.00. Stored in Buffalo. Address Box 684, c/o Aerial Age Weekly, 5942 Grand Central Terminal, New York City.

JN4Ds WITH NEW OX5 MOTOR $1250.00 Buffalo. Floyd J. Logan, 716 West Superior, Cleveland, Ohio.

NEW OX5 Curtiss Hammondsport motors boxed complete. Log book, inspection sheets, $475.00 each F.O.B. Chicago. Lee Hammond, 30 No. Michigan Ave., Chicago, Ill.

WE HAVE FOR SALE seven Canucks, all in good flying condition. Prices range from $600.00 to $1000.00. Service Aviation Company, Wabash, Indiana.

FOR SALE—Canuck just overhauled A-1 shape $800.00. Joe Esch, 289 West Center St., Akron, O.

FOR SALE—JN4D with OX5 motor A-1 condition $800.00 for quick sale. Joe Esch, 289 West Center St., Akron, O.

HURRY!! LAIRD SWALLOW, nearly new, with photographic contract. Standard J1 and Canuck with passenger carrying contracts. These contracts for immediate acceptance and will give you a big start for the season. Hangar, extra motor, spares, etc., all in pink of condition. Priced right. Sell all or part. Take the first train. Heddon Aviation Co., Dowagiac, Mich.

FOR SALE—New Liberty motors and parts, reasonable price, immediate shipment. Also brand new Curtiss OX5 cylinders. Address Grant Motor Co., 912 E. Grand Blvd., Detroit, Mich.

FOR SALE—One aeroplane, absolutely new, never used, Thomas Morse 34C complete with Le Rhone engine 80 H.P. $875.00 F. O. B. Newport News, Virginia. Must be sold at once. Address Benj. Fisch, 4215 Huntington, Ave., Newport News, Virginia.

FOR SALE—Six 9-cylinder 140 H.P. rotary motors at $50.00 each; $250.00 for the lot. Also Liberty, Hispano and OX5 motors and parts. W. F. Long, San Antonio Aeronautical School, Stinson Field, San Antonio (Route 1), Texas.

CURTISS SEAGULL, dep. control, K-6 motor, good flying condition. Price $2000.00. Also other types for sale. Curtiss Flying Station, Atlantic City, N. J.

SIX PASSENGER HS2 BOAT in perfect flying condition with Liberty motor. Very cheap for cash. M. W. Blasier, 54 Water St., Auburn, N. Y.

PLANES OF ALL KINDS
1 to 5 seaters—$450.00—$2500.00
27 SOLD IN 5 WEEKS—THEY MUST BE GOOD
Chamberlin Aircraft
Hasbrouck Heights N. J.

RELIABLE PILOT AND MECHANIC wishes position. Three years of commercial experience. Best references. Address Hugh C. Robbins, P. O. Lock Box No. 6, Williamsburg, Ohio.

FOR SALE—Three passenger aeroplane, fully equipped, or will consider a good auto in trade. Lock Box 198, Burlington, N. J.

SEVEN CANUCKS FOR SALE — Excellent flying condition. $500.00 to $900.00. Service Aviation Company, Wabash, Ind.

THREE GOOD COMMERCIAL PILOTS wanted immediately. Should have cross country experience. Write for particulars. Service Aviation Company, Wabash, Ind.

CURTISS COMMERCIAL H 180 Wright 3 passenger. Just remodeled and recovered. Worth $2500; less for cash. Fay & Ross, 3503 E. 26, Kansas City, Mo.

WANTED—A partner with an aeroplane or M. F. boat, either experienced or inexperienced to carry passengers. Address Box 682, c/o Aerial Age Weekly, 5942 Grand Central Terminal, New York City.

PILOT, RIGGER, MECHANIC—Wishes connection with company or private owner doing commercial flying. B. M. Paul, 6504 So. State St., Chicago, Ill., c/o Chas. H. Paterson.

MODEL AEROPLANES AND SUPPLIES— Let us supply you. Send for our latest catalog. 10c brings it to you. Wading River Mfg. Co., 672-AB, Broadway, Brooklyn, N. Y.

BREGUET, with brand new extra set newly covered wings, 300 Renault, only flown 5 hours, lots engine spares, radio equipment, duralumin fuselage, reinforced glass bottom for photography, dual control, 7 hrs. gas supply, 3 propellers. Speed 27-120 m. p. h. climb over 1000 ft. per min. Gas consumption 13½ gals. at 85 m. p. h. All American wires and turnbuckles. Rear cockpit can be built to accommodate 3 people. Useful load 1700 lbs Ship ready to fly away. Box 22, Osborn, Ohio

Why Are ERICSON'S PRICES So Attractive?

Because they are absolutely the lowest, considering the quality of the material.

Extract from our price list:

OX5 Parts

8	Pistons with Rings	$20.00
16	Piston Rings	2.00
	Carburetor (Zenith)	15.00
8	Valves	7.00
16	Valves	12.00
	Connecting Rod, each	3.50
	Set of Connecting Rods (8)	20.00

Canuck, JN4 and Avro

Wing Panels, covered, each	$95.00
Landing Gear, complete	75.00
Propellers for OX5 (boxed)	15.00
Wheel with Tire and Tube, each	12.00

NOTE. Prices quoted at Buffalo. Duty Paid

Be your own jobber and buy direct from us.

MF FLYING BOATS

We have purchased from the Navy all the remaining MF Flying Boats, 57 in number.

These are new, unflown and in perfect condition.

Our prices are:

MF Flying Boat, without engine, f.o.b. Philadelphia or f.o.b. Pensacola, Fla. **$675.00**

MF Flying Boat, two seater, with 100 H. P. OXX6 motor installed, ship completely tuned up and ready for flight, f.o.b. College Point, L. I., N. Y **$1700.00**

MF Flying Boat, reconverted to 3 seater, equipped with 150 or 180 H. P. Hispano, f.o.b. College Point, L. I., N. Y. Model CK-14 .... **$2900.00**

This is a **real opportunity,** probably the last of its kind.

Correspondence with Distributors invited.

BUY IT FROM THE NAVY

Sealed proposals will be opened

11 A.M. JULY 18, 1922

(Standard Time)

For the Purchase of Aviators' Equipment and Clothing. Consisting of the following:

2,700 PAIRS BOOTS

Fleece lined, knee, leather sole and heel. Packed 70% one pair per box, balance tied in pairs. Sizes 8 to 12.

940 PAIRS BROGANS

Canvas top with heavy leather hobnailed soles and heels. Sizes 7 to 12. Packed 80% one pair per box, balance tied in pairs.

270 COATS

42 inches long, with removable lining of heavy fleeced jersey. Six buttons with two straps at collar. Sizes from 34-36 to 42-44.

1,350 PAIRS GAUNTLETS

Black sheepskin, with removable all wool mitten inside, three finger, adjustable cuff. Sizes from 8 to 10½.

340 HELMETS

Hard outer case, with sheepskin lining, ear tubes attached. Sizes 6¾ to 7½. Packed one per pasteboard box.

780 PAIRS OVERALLS

280 are made of leather-tex, with moleskin lining. The remainder are the very best of overalls, heavy fur-lined, belted, with straps to close at ankles. Manufactured by Maison Lemercier, Paris. Sizes 36-44.

Make your selection. Bids will be considered for any lot or all lots or any part of any lot.

Inspection is invited before bidding; samples may be seen at Naval Supply Depot, Brooklyn, N. Y., or Central Sales Office, Washington. Catalog No. 102-B, giving complete information, may be obtained from the above mentioned offices.

Learn *to* Fly

Aviation is making such strides that it needs more men right now

You Can Learn To Fly

I can teach you how to become a successful pilot in a short time. My course is so arranged that you get only the things you need to make you a good aviator.

The Diggins Extension Course

is up-to-date, teaches you what you must know to become an expert flyer. This course is written by competent instructors right on my flying field. It is kept right up to the minute—all new developments in aviation are included. That is why it is recognized as the most complete and practical course offered today. My course saves you time and money because it prepares you at home so that you are ready to begin flying the day you arrive at the flying school.

Superior Points of the Diggins School

1. The Diggins school is the oldest, largest and most complete commercial aviation school in America.
2. The Diggins school is located in Chicago, the center of Aviation.
3. Living quarters and free employment service are maintained for students.
4. Diggins guarantees to make you a pilot.
5. Diggins' pilots get top notch salaries.
6. References, any aero club in America.

WRITE TODAY Write today for the new Diggins beautifully illustrated catalog.

The Ralph C. Diggins School of Aeronautics

Dept. 8 140 N. Dearborn St. Chicago, Ill.

Please send me the Diggins catalog and information about the Diggins flying course.

SPECIAL OPPORTUNITY

To Secure a Copy of the

Textbook of Aero Engines

By E. H. SHERBONDY and G. DOUGLAS WARDROP

Together With One Year's Subscription to

AERIAL AGE WEEKLY

The Leading Technical and Trade Aeronautic Publication in America

The Textbook of Aero Engines has been prepared for the purpose of having in one volume the complete information concerning all modern types of aero engines and an up-to-the minute discussion of the principles of aero engine design and construction, so that the reader may be able to undertake comparative research without recourse to a formidable list of volumes and publications, which in any event could only supply him with more or less obsolete information.

AERIAL AGE WEEKLY discusses and describes all current developments in the aero engine field, so that with the Textbook and consecutive copies of AERIAL AGE the subscriber will possess a complete encyclopedia on the subject.

To AERIAL AGE WEEKLY
5942 Grand Central Terminal, New York

Please send me a copy of the Textbook of Aero Engines (regular price $10.00), and enter my name on your subscription list for one year (regular price $4.00). I desire to take advantage of securing both at the special price of $10.00, and am enclosing my check for that amount herewith.

AN AMERICAN DEVELOPMENT IN LARGE BORE AIRCRAFT ENGINES

The Wright D-1 is a distinctively American engine developed for the propulsion of lighter than air machines, recently completed for the U. S. Navy Department.

This is the largest heavy duty aircraft engine developed to date and is designed particularly for use in ships of the Zeppelin type.

The D-1 marks a very high engineering point of achievement in lighter than air aeronautical propulsion.

FIRST

- Wherever aeronautical engineers or the traveling public gather and discuss Commercial Aviation in America, the outstanding feature of their talk is that the predominant Company today is AEROMARINE

- This enviable reputation has been earned by the products of the AEROMARINE plant at Keyport, New Jersey, the sales promotion and educational campaigns carried on throughout the United States by the AEROMARINE ENGINEERING & SALES COMPANY and the brilliant performance of the AEROMARINE AIRWAYS, the largest commercial, aerial transportation Company in the world operating flying boats.

The public has faith and confidence in AEROMARINE. The white flying boats with their distinctive black tails are known all over the world as dependable, safe aircraft, properly manned and operated.

You can own and operate an AEROMARINE flying boat - we have a limited number of the FAMOUS AEROMARINE-NAVY HS LIBERTY ENGINED TYPE for sale at reasonable prices. Write for illustrated, descriptive pamphlet and booklet "What They Say About The Aeromarine Flying Boat Service".

Contracts Still Available to Responsible Dealers

In the field of commercial aeronautics the PETREL is unique in design and construction, in performance, and in economy of maintenance and operation.

It was designed and developed by Thomas H. Huff, whose experience since 1915 in aircraft production, during the war in aeronautical engineering in an advisory capacity with the U. S. Air Service, and after the war in direct connection with the Naval Aircraft Factory, has qualified him to lead the way in progressive aeroplane design.

The PETREL has been a gradual, certain evolution. During nearly two years of its development careful selections and alterations have been proved by test, and have brought it to its present state of high efficiency.

The PETREL is manufactured by workmen old in the best traditions of aircraft production, and proud of their craft. Every smallest part is selected from the same source, and worked on the same benches, by the same hands, which construct Huff Daland aeroplanes for Army and Navy, under direct government inspection and supervision.

The PETREL has been tested, flown and accepted by the Air Service. It is the only commercial aeroplane in production in this country of which this statement is true. Its simple design, its freedom from wires and turnbuckles, and its rigidly braced fuselage combine to cut maintenance costs to the bone and assure a plane whose correct alignment and absolute rigidity are limited only by its long life. And its superior performance gives you more speed or more distance per unit of power expended than you can get with any other three place aeroplane in existence.

Its specifications and performance with full load are guaranteed:

	OX5 Motor	Hispano Motor
Span	**31′ 00″**	**31′ 00″**
Height	**9′ 00″**	**9′ 00″**
Length	**24′ 00″**	**24′ 00″**
Weight Empty	**1125 Pounds**	**1215 Pounds**
Useful Load	**735 Pounds**	**750 Pounds**
Radius	**300 Miles**	**350 Miles**
Climb in 10″	**4500 Feet**	**8000 Feet**
Ceiling	**12000 Feet**	**18000 Feet**
Maximum Speed	**90 MPH**	**110 MPH**
Minimum Speed	**35 MPH**	**38 MPH**

FORESEEING THE AIRPLANE'S NEEDS

Copyright 1922, by The Goodyear Tire & Rubber Co., Inc.

Goodyear's ability to provide equipment for the largest aircraft of today is the result of our long and close association with aviation, and our sincere desire to assist this new industry.

For example, the 44 x 10 Goodyear Airplane Tire was designed and built far in advance of actual need. And the requirements of the future already have Goodyear's consideration.

And like every other Goodyear product, Goodyear airplane equipment is worthy the service required of it. It is specially designed and carefully built to insure maximum safety and efficiency.

Goodyear's part in the development of lighter-than-air craft is known to every airman.

Achievement!

It is a fine thing to excel in any given endeavor—but it is a finer thing still to achieve success in a field in which precedent has placed no milestones.

To have achieved the success that has come to Curtiss has been no trick of Fate. Rather has it meant a stupendous job and a faith in ourselves inborn through a knowledge of the task.

Our successful result is visualized in the hundreds of different ways in which the Curtiss products are used throughout the world, establishing new industries, offering new opportunities, until today Curtiss stands for all that is best in aviation.

Everyone knows that Curtiss Aeroplanes combine

RELIABILITY
STRENGTH
PERFORMANCE
ECONOMY
COMFORT

They are the standard of the world. Pilots know that the Curtiss reputation is their protection and consequently the best and most successful flying organizations in America are today using Curtiss Aeroplanes and Motors. Flying schools, aerial photography, aerial advertising, Curtiss Sales and service are only a few of the many profitable business opportunities open for live business men and pilots.

Commercial and Military Aeronautics

By WILLIAN KNIGHT, M. E.

SEVERAL criticisms have been made from time to time on the matter of the more or less perfect adaptation of the military flying machine which was practically born and developed during the war to the needs of post-bellum commercial aviation.

"The Commercial aeroplane does not exist in America" was the surprising statement attributed to one of our best flyers a few weeks ago after unsuccessfully attempting a cross-country flight on a good machine which has successfully stood the more severe tests both in Germany where it was born and in this country where it has been adopted by Larsen.

It is out of question that the commercial aeroplane of to-day is far as yet from being the ideal means of transportation in the air, but this is not a good reason for condemning the present day commercial aircraft and for casting a shadow of doubt on its present and future possibilities.

So far as commercial aviation expenditures, even in France where the Government has taken an active interest in its development that has not been equalled by any other government, have stood a very poor comparison with military aviation expenditures. Two hundred and forty-six millions of francs for military aviation and forty-five millions for commercial aviation are such figures that explain quite eloquently why the military flying machine has progressed since the war at such a rate which cannot be compared to the progress made by commercial aircrafts.

To this country, the comparison is even more discouraging because the only money that we are opening at the present time for commercial aviation is the money which is being spent for keeping alive what remains of our air mail service.

The development of a truly commercial aircraft, quite evidently requires money. Aircraft manufacturers in this country are not generally inclined to invest large sums of money in experimental machines radically new, without any subsidy being paid by the government for that purpose.

Aircraft manufacturers in Europe are doing their best to develop new commercial types of aircraft in spite of the fact that they find themselves seriously handicapped by some features that they have to include in their designs in order to be able to collect from their governments those subsidies that they cannot afford to dispense with at the present time.

On the other hand, however, if the aerial operating companies in Europe had waited for the perfect commercial aircraft to make its appearance before starting operation, nobody at the present time would be flying from Paris to Casablanca and to Warsaw in twenty-four hours and from Paris to Constantinople in two and a half days.

If marine, automotive and railroad engineers had seeked the perfection before attempting operating engines that they knew quite well had to be further developed and perfected, we would have never had the steamship, the automobile and the railroad train, because the only way how to perfect a mechanism is to use it first as it is and see after what is needed to improve upon it.

In 1911 after the raid made by Paulhan d'Orleans at Arcis-sur-Aube somebody suggested to a well known high rank French officer who was in charge of aeronautical developments at the Ministry of War, that the time had come for organizing some military air squadrons, the answer was: "Wait, wait, do not run so fast with your imagination; the aeroplane is far as yet from heing in such a shape as to warrant its use in the army." And this happened only three years before the war started.

If we had waited for development of ballistics before building and using guns we would probably have now the same armament which was used by the Indians.

Thirty-five years were needed before reaching the present stage of development of the steam locomotive, twenty years were required to perfect the marine engine and fifteen years have been spent in perfecting the automobile. Do the critics of present day commercial aviation propose to wait twenty years before considering the aeroplane as a safe and efficient means of transportation?

Such critics are ready to concede that the aeroplane is an efficient war engine, but connot separate in their mind the military from the commercial arcraft. This is an error. The divorce of commercial aviation from military aviation is absolute, and it has been recently sanctioned in the note sent by the allies to Germany concerning the resumption of German commercial aeronautical activities which, it has heen decreed by the allies, must be based on the following conditions to be fulfilled by the German aircraft manufacturers: Ceiling 4,000 meters; speed at 2,000 meters altitude, 170 kilometers per hour; fuel for 3 hours flight; useful load 600 kg.

These conditions very nearly represent the average present state of affairs in commercial aviation and mark the heginning of the application of a sound economical regime for commercial aircraft.

Military aviation, on the other hand is progressing along an entirely different road: a pursuit aeroplane must be able to climb rapidly to 25,000 or 33,000 feet altitude and fly horizontally at 170 miles per hour; a bombing aeroplane must also be able to climb up to high altitudes with several tons of bombs on board and must be able to cover without stopping 500 miles or more.

At first sight the bombing aeroplane seems to be the best type which can be adapted to commercial exploitation. It is very often stated that the price of the ton-mile decreases with the increase of the load carried. These conclusions are arrived at through the mistake which is often made of comparing the aeroplane to a ship. A ship floats on the water without any need of motive power, while instead an aeroplane needs motive power in order to sustain itself in the air. Also the ratio between useful load and total load of a ship, for the same speed, increases with the dimensions of the ship whereby in an aeroplane this ratio remains practically constant.

An average attained by figuring on the characteristics of all sorts of aeroplanes, except scouting aeroplanes, shows that the load lifted by the present day flying machines is from 14 to 16 lbs. per h.p. or from 9 to 11 lbs. per square foot of lifting surface irrespective of the dimensions.

These are the fundamental basis which determine the separation of military and commercial aviation and it is an error to assume the interdependence existing between these two well defined and entirely separate phases of aerial navigation.

To talk about building commercial aircraft which in case of a national emergency can be efficiently adapted to military uses is a very optimistic talk. Of the 598 commercial aeroplanes now in use in France only a very small percentage could be used for military purposes and this fact is well recognized by French and other aeronautical experts.

We think that these facts should be stated and that it should be dispelled the delusion under which we are inclined to live that by developing commercial aeroplanes which repre-

Digitized by Google

sent a compromise between commercial and military exploitation we are helping to build a powerful aerial defense at the same time that we provide for a fleet of efficient aerial commercial carriers.

The problems of military and commercial aeronautics are entirely separate the ones from the others and to put commercial aeronautics in this country under the control of military aeronautics as is the case in France, for instance, would be a mistake. What we need is a department of aeronautics, separate from both the Navy and the War Departments which will consider the problems of civil aviation from an entirely civilian standpoint.

But above everything else what we need now is to stop talking about commercial aviation and the limitation of present day commercial aeroplanes and start operating commercial lines with whatever commercial flying equipment we have at the present time. This is the only way that we can ever hope to develop aeroplanes well adapted to commercial uses.

Aircraft manufacturers who at the present time are living on government jobs will give to us the commercial aeroplanes that we need if we can show them that there is a field for such a production. We cannot expect aircraft manufacturers to design and build for us such aeroplanes without any subsidy on the part of the Government and without any organized commercial activities in this country.

Let us get busy, let us start doing something constructive for establishing civil aviation in the United States on sound business basis.

Remarkable Performance of the Loening Air Yacht

THE Loening Aeronautical Engineering Corporation delivered the air yacht ordered by Mr. Vincent Astor on schedule time, with no delays whatsoever, and the machine was flight tested by David H. McCulloch at Port Washington on June 19th and 20th, so that Mr. Astor, on his return from Europe on June 23rd, found his machine entirely ready for him.

He arrived on the Mauretania about eleven o'clock in the morning and after spending some time in the city, motored to Port Washington, and flew on his air yacht in about 50 minutes to New London, arriving there in ample time to see the Yale-Harvard boat races.

No other means of travel could have accomplished this result.

Several of Mr. Astor's guests took flights in the new machine after its arrival—a party of them returning to New York quite late the same night, arriving after dark.

Clifford Webster is pilot of the Astor Air Yacht and on June 26th flew up to Poughkeepsie with Mr. Astor and a party to attend the intercollegiate boat races there. The trip from New York to Poughkeepsie was made in about 50 minutes, and the return trip in about 40 minutes—most of the trips being made at a cruising speed in the neighborhood of 110 miles an hour.

The Astor Air Yacht differs only in detail from the original model of the Loening Air Yacht. The seating arrangement has been modified and a complete dual control system installed as Mr. Astor will fly the machine himself from time to time. The door to the cabin, formerly on the side, has been placed in the bow, and many detail arrangements, such as the anchor and other equipment, have heen greatly improved upon.

Special lockers for goggles, helmets, etc., have been provided.

Structurally the new flying boats are virtually the same, with the exception that the wings themselves have been increased in area, and in the interior of which all metal fittings have been doubled in thickness in order to give ample margin for the possibility of rusting.

The bottom of the hulls are made of an aluminum alloy, treated inside and out with a special marine glue preparation to prevent deterioration from salt water.

The new machines also have a larger gasoline capacity—Mr. Astor's air yacht carrying enough fuel to fly it non-stop for 500 miles.

The finish of the Astor machine is, of course, specially chosen by the owner. The color is a light grey, with dark grey finishing lines. The wings are treated with pigmented aluminum colored dope and the interior of the cabin is fitted with blue leather upholstery and light varnish woodwork finish.

The owner's private signal—a red star on a white field—flies at the mast, which also serves to hold the speed indicator tubes.

The instrument equipment is complete with compass, drift indicator, gas and oil pressure gauges, thermometers, tachometer, altimeter, air speed meter, etc.

The actual delivery of Mr. Astor's Air Yacht was of considerable interest, because the Loening plant, where this machine was constructed, is equipped with special Ogden type doors which, when raised up, form a clear opening 46 feet wide and 18 feet high. This is the largest opening in any building on Manhattan Island. It was thus possible, after the final assembly of Mr. Astor's machine in the factory, to wheel it out of the doors and on to the dock, where it was hoisted aboard a lighter and brought to Port Washington completely set up and ready for its initial flight tests. This is the first time that a fully set up aeroplane ready for flight has been brought out of a building in New York City.

There has been a great deal of flying lately on the Loening Air Yacht in this vicinity.

One of the most interesting experiences in this connection was had recently by Mr. Harold S. Vanderbilt, Commodore of the New York Yacht Club.

Mr. Vanderbilt has been flying with Mr. David H. McCulloch on the Loening Air Yacht ever since its return from Palm Beach and has made many trips, some as far as Marblehead, Mass. The following schedule, all done in one day, shows the remarkable ability of machines of this kind to cover long distances.

On Monday, June 26th, Mr. Vanderbilt played 18 holes of golf at the National Golf Links at Southampton, Long Island. He left there, accompanied by three friends, at about 12:30, with Harry Rogers piloting the Loening Air Yacht, and landed at 82nd street and the Hudson river in 52 minutes. This is a distance of approximately 95 miles, so that the average cruising speed was about 120 miles an hour.

The party lunched at the Columbia Yacht Club and then went to the Polo Grounds to attend the Yale-Harvard baseball game, leaving the Air Yacht anchored in the river. They stayed until the end of the game and then returned to the Columbia Yacht Club, where they again boarded the plane and proceeded to fly to Poughkeepsie to attend the 'varsity boat races, arriving there in time to see the entire race.

The party left Poughkeepsie about 7:15 and arrived at Port Washington, Long Island, about 45 minutes later, in time for dinner on Long Island.

Mr. Vanderbilt has ordered a Loening Air Yacht for his own use and this machine will be delivered to him about the middle of July and will be piloted hy Harry Rogers.

A Challenge to the World

A CABLE dispatch to the Air Ministries of Great Britain, France, Italy, Spain, Portugal, Belgium, Norway, Sweden, Denmark, Cuba, Mexico, Brazil, Argentine Republic, Chile, Peru, Japan and China, over the signature of Rear Admiral Bradley A. Fiske, U. S. N. retired, challenged the aeronautical engineers and sportsmen of those powers to enter into a competition with a similar American group to circumnavigate the world with a commercial hydroaeroplane of one hundred passenger capacity.

This action disclosed the fact that a large group of American engineers have reached the conclusion that the era of commercial navigation on a big scale is at hand and that they have carried experimentation to a point where the design of the American entry for such a competition has been tacitly accepted. Details for financing and building the enormous flyer have been worked out and the group is prepared to put their scientific conclusions to a practical test by precipitating the international contest.

The challenge to Great Britain, of which those to the other countries are practically duplicate, follows:

"Please convey to representative group of British aeronautical engineers and sportsmen the compliments of American group affiliated in the project to build hydroaeroplane of hundred passenger capacity to circumnavigate the world for advancement of commercial aerial navigation. Stop. Also please convey friendly challenge to compete with British ship. Stop. Conditions of contest and details by mail upon receipt of assurances of entry.

The challenge followed the organization of the group as a trust estate under the name of "The American Eagle"—which has been adopted for the name of the airship when completed. Among the prominent engineers, aeronautical experts and scientists included in the group the following were mentioned yesterday by Secretary Cyril O. Assmus, in announcing the issuance of the challenges: Charles W. Burrows, Ph. D.; Charles H. Day, A. E. M.; Duval La Chapelle; Frederick Charavay, M. E.; I. S. Kaufman, B. S., C. E.; I. E. Glover, B. S.; J. H. Steenson; Joshua Ward, B. S., M. E., and Captain Hugo Sundstedt.

The latter has been named designing engineer of The American Eagle and his preliminary draft has received tacit acceptance. Captain Sundstedt's achievements in aeronautics have been international in scope. He left a naval career to take up aeronautics with Bleriot in 1909 and was later associated with Farman. During the war he was chief test pilot in the French Air Service. He holds honors for having made the first trans-Baltic Sea flight and Paris-Stockholm flight, among many others, and has been identified with American aeronautical activities since the close of the war.

Dr. Charles W. Burrows is a consulting engineer in New York with laboratories in Newark, N. J. He was formerly chief of the Magnetic section of the U. S. Bureau of Standards at Washington, in which post he served with professional distinction during the war, having been called to it from the department of physics at the University of Michigan. Dr. Burrows has accepted the post of Administrative Engineer and will pass on every detail of the construction and equipment of The American Eagle.

The board of consulting engineers

Airscape of the Stock Farm of Governor Warren McCray at Kentland, Indiana

Digitized by Google

includes Charles H. Day, who, as chief engineer, designed the J-1 for the Standard Air Craft Corporation and built the American Handley-Page-Caproni bomber. He is engineer in charge of structure. Duval La Chapelle, who was with Orville Wright in France and is recognized as an authority on pontoons, which constitute his especial responsibility with the American Eagle. Frederick Charavay, M. E., among the foremost designers and experts on propellers is consulting engineer on this phase of the huge American plane.

F. A. Robertson, chief engineer of the Splitdorf Electric Company, and a recognized world authority on ignition, is in charge of electrical design and installation, and associated with the foregoing in charge of power plant, controls, material, instruments and aerodynamics, are engineers and experts whose names have not as yet been made public.

The partial personnel of the engineering staff given out by Mr. Assmus includes I. S. Kaufman, B. S., C. E., who has been active as a aeronautical engineer since 1910, and who served during 1918 and 1919 with the U. S. Army Engineering Corps, receiving a prize from the U. S. Government for designing a successful night bomber; I. E. Glover and James H. Steenson, who in addition to eleven years' experience in aeronautical engineering, devoted two years to exhibition flying and passenger piloting. Joshua Ward, B. S., M. E., was named as the Washington representative and Col. Evan Shelby as counsel.

Despite the naval and military tinge to the personnel, the American Eagle project and the competition it has invited are described as approached purely in the spirit of sportsmanship on the premise that the contest will blaze the way for larger scale aerial commercial activities of an essentially peaceful nature and hasten the adoption of aerial cruisers for trans-oceanic passenger, mail and express business. This aspect is emphasized by the past activities of Secretary Cyril O. Assmus, through whom the announcement was issued, and who has organized and directed many cruises for the British Royal Mail Steam Packet, and the Hamburg-American companies prior to the war. The latter said of the project:

"This undertaking is simply and obvious development of the day—an elaboration of what has been done and is being done on a smaller scale. Experimental 'stunt' and 'gypsy' flyers have paved the way so thoroughly that a large number of American aeronautical experts came to the conclusion that only concerted action was necessary to circumnavigate the globe with an airship of practical commercial size to settle once, and for all time, the question of the scientific mastery of the air for other than destructive purposes.

"Work on The American Eagle has progressed in a quiet way over a considerable time. Reports of similar efforts abroad reached our ears and after deliberation it was agreed that the most manly and sportsmanlike method of approaching the subject was in laying our cards on the table for all the world and to invite international competition. This will go far to clarify the status of various prizes that have been offered from time to time for this feat, and doubtless will result in the offering of other prizes and trophies by the sportsmen of the world. It will also serve to stimulate a friendly constructive interest and enthusiasm among those who realize the airship will supplant the ocean liner for first cabin passenger, mail and express business, as distinguished from those who see in the aeroplane only an agency of war and destruction.

"We feel that we have no accasion to fear that American ingenuity and constructive genius in this field cannot hold its own against the world. In this connection the names that have become public do not tell the story of the personnel group in this project. Every inventor, engineer or manufacturer who has anything of value to offer, may contribute his idea or feature without sacrifice of proprietary rights. It will be tested for efficiency and if of superior value, will be used, making the American Eagle a great American aeronautical laboratory or clinic.

"Negotiations are pending with many prominent men and organizations for whom we have no authority to speak at this time because the negotiations have not reached the stage of completion. Now it's up to the world to try to beat America in this field."

The Pegna-Rossi-Bastianelli Seaplane. The machine, which is of nearly 100 feet span, is intended to carry a very large proportion of disposable load at the high cruising speed of 100 m.p.h. It is equipped with four Isotta-Fraschini motors of 270 H.P. each, arranged two in tandem in each of the two wing nacelles.

The Berliner Helicopter

HAVING perfected a helicopter which will rise gracefully from the ground and glide forward with the same precision as the most advanced type of aeroplane, Henry A. Berliner, a Washington inventor, is now busily engaged in further perfecting his vertical-rising airship so that it will alight with a degree of safety that will make it available for peace or war-time purpose.

The Berliner helicopter has undergone a series of tests at the flying field at College Park, Md., a suburb of Washington, before high aviation officers of the American Army and Navy and military attachés of foreign governments stationed here. All have pronounced the machine a success. In all the tests Berliner, the young inventor, has piloted the helicopter, which is capable of rising vertically from a standstill to a height of twenty feet and then advancing in a forward direction around the field without loss of distance from the ground. The machine, it is said, responded perfectly to Berliner's demands while in flight, but the inventor has not yet perfected the machine to the extent of landing from any height with the degree of safety that is required.

"We have demonstrated that our machine can rise vertically from the ground and we have further shown that it can move forward and is capable of control in flight," Mr. Berliner said today, "but the problem of landing safely is yet to be solved. Once this is solved I believe the helicopter will become as practical as the present-day aeroplanes, with the added feature of taking off in small areas and possibly landing in the same restricted zone."

Bringing New Machine to Earth Is Problem

Mr. Berliner would not discuss the possibility of entering his invention in the competition for the $250,000 prize offered by private British interests for the perfected helicopter. He said, however, that if he perfects his machine so that it will land with safety the future of the helicopter is assured.

Bringing the machine to earth safely, therefore, is the hig problem that Berliner has set out to solve. The machine as now designed comes down with a rock-like fall when the motor is cut off. With an engine of extreme nicety of adjustment and absolute certainty of action descent might be made by simply throttling down the propeller speed gradually. As there is no engine of such dependability, other means must be found by Berliner.

The use of parachutes or any balloon-like aid would add too much weight to the machine. Another method proposed is that in coming down the propellers he so built that they can be disconnected from the engine and the angle of the blades changed so that they will offer greater resistance.

The Berliner machine resembles an aeroplane without wings. The fuselage and rudder are the same, and a Lerhone 110-horsepower rotary motor is mounted forward as in an aeroplane. On either side of the fuselage there is an upright carrying a 14-foot propeller. These two propellers revolve in opposite directions and force the air downward, lifting the 1,400-pound machine and pilot off the ground.

Near the tail there is a small propeller, which is geared also to the motor and which tilts the entire helicopter by slightly lifting its tail. This tilt causes the forward motion of the machine. The inventor claims that with a 1,000-pound load but 3 per cent of the lift is lost in a tilt of 15 degrees, and that this loss is transferred into horizontal push of ahout 25 per cent of lifting power. This is a somewhat greater tilt than has been used in most of the experiments, hut he thinks that a 25-degree tilt may possibly be reached safely.

Idea Follows Plan Worked on by Father

In evolving the helicopter Berliner has heen preceded by his father, Emile Berliner, an inventor, who took up the old idea of constructing a machine that could rise vertically from a standstill about twelve years ago. Since then he had been experimenting, building and rebuilding it, until he was forced to give up the task about three years ago on account of illness. Henry, who is twenty-six years old and was graduated from the Massachusetts Institute of Technology, then took up the work and succeeded in making the first flight in a machine of that type.

The success of the machine is due, in part, the inventor said today, to the size of the two propellers that are placed on the machine in a position that would correspond to the outer wings of a biplane. Many have tried to use mammoth propellers, some as long as fifty feet, he said, but they derived no results.

The Berliner Helicopter in Flight

Digitized by Google

Once in the air, the helicopter moves forward with the aid of a three-foot propeller attached to the tail of the machine, which tilts it downward.

The body or fuselage, which is about twenty feet long, was taken from an aeroplane, and likewise the rudder, which guides the machine from left to right. Both father and son believe the machine has wonderful potentialities. They point out that this type of aeroplane would be especially advantageous to the Navy, as the seaplanes and flying moats now in use require a long stretch of water as a "take-off."

The helicopter, or vertical-rising air machine, is not an impossibility, and should a real use for such type arise successful ones may be seen before many years, according to Dr. Albert F. Zahm, aeronautical expert for the Navy, in an interview with the Associated Press. Had there been a need for the helicopter during the war, he said, any of several types could have been perfected, of which working models have been flown.

Dr. Zahm is an expert on design and construction of all manner of flying machines. For years he has applied his time to perfection of the aeroplane, and is well qualified to pass upon the capabilities of any.

Much interest has been shown of late in reports of successful machines of the helicopter type being perfected in both Germany and England. However, while some flights have been made, none of any consequence are reportd by a machine equipped with horizontal propellers or revolving planes, designed to rise vertically from a confined space and descend on the same.

That the helicopter is possible, Dr. Zahm said, is proved by the German machine, which, rising several times to moderate heights, has carried observers, remained almost stationary while in air and descended in safety. The machine, however, has made no extended flight, such as would prove its dependability, but was tethered to the ground by a mooring rope. At times, when the motors failed, the machine dropped and the passengers saved themselves only by leaping with parachutes.

The experiments are continuing, however, with the purpose of perfecting a motor which can be depended upon to maintain the machine without sudden failure, the scientist explained, for as soon as the engine stops the machine cannot glide to the ground, as does an aeroplane, but drops vertically. In a proper descent the propellers should be whirled slowly to ease the landing.

Present hopes of attaining successful vertical flight rest mainly upon the endeavors of Mr. Berliner and of Louis Brennan, of London, whose newest machine is reported as nearing completion. He is working to win the £50,000 prize offered by the British Air Ministry for successful flight.

The helicopters upon which most experimentation has been made consist mainly of two or more propeller screws mounted horizontally on a vertical shaft, bearing engines, fuel and passengers. Equal numbers of propeller blades must revolve in opposite directions that the body of the machine may not spin like a top. The motors, tanks and body have been mounted in various positions, but the German machine has a sort of pulpit car mounted at the top of the shaft over the propellers for the operators.

Other Types of Vertical Flying Machines Offered

Whether or not this type of machine is brought to actual use, Dr. Zahm stated, at least two other types of planes that may fly vertically have been offered to the Government. This fact is not widely known.

One of these, of which Dr. Zahm observed experiments with a working model, was almost identical with the present type of plane, except that mounted behind the body were two sets of air vanes, in groups, tilted at an adjustable angle, like that of Venetian blinds.

When the power was turned on, he said, the "wash" of the air stream from the propellers pushing against these groups of vanes caused the model to rise gently vertically. The model was held in midair by the action, and when the power diminished it returned gently to earth. A full-size machine of the type, he said, would be equipped with engines of immense power in order to furnish sufficient air pressure, and when driven to a sufficient altitude the vanes would be so adjusted that horizontal motion would result. The plane could then fly in the usual manner, finally using the vanes again to descend vertically.

The other type offered to the Army, he said, was of the present wing plan, equipped with three propellers, two placed far out toward the wing ends and with vertical rudders and ailerons similar to those in use. The quicker lifting power was to he gained by having the wash of the central propeller act upon elevators on the tail of the body, while the side propellers would wash against the special ailerons on the wing tips.

When in the air, Dr. Zahm continued, this machine could maneuver exactly as does the ordinary plane, cut figures and do "stunts," besides being able to rest motionless in any desired position—vertical, with nose up, if need be.

The best feature, he said, is that both planes of the new types are entirely feasible and can be constructed at any time. In fact, several European inventors and manufacturers are patenting designs of the second type, notably the Frenchman Bleript, one of the pioneers of aviation.

Cost and Weight Called Drawbacks to Construction

Experts for the Government studied the second type during the war, it was explained, but the matter went no further.

The general drawbacks of their construction, Dr. Zahm said, were, first, the great cost; second, the increased weight of the machines as compared with present engine efficiency; and, third, the need of developing motors with greater power and less weight per horsepower and with a greater amount of dependability. As it is, he said, a successful helicopter may be flown to any height, but the operators will never know when the engine will give a cough and die away.

The German experimenters, however, he added, have in part overhalanced this disadvantage. It has been determined by experiment that a propeller of three or four narrow blades, caused to revolve by the air pressure resulting from a forced descent with a dead engine, will develop as much parachute resistance as a solid disc of the diameter of the blade spread. In addition, the German machine is equipped with air cushions on the landing bottom so that the landing, if forced, may be made comparatively easy.

Means of steering experimental helicopters, and of which one would undoubtedly be used in a successful machine, are two. The first is a means of tilting the propeller's shaft or the whole machine, when it will travel in that direction; the second being the use of vanes similar to those already described. With the latter, Dr. Zahm thinks, a helicopter sufficiently powered should be able to cut capers in the air as aviators do at present.

Any of the types advanced would, in warfare, be of great use in bomb dropping or for observation. The main disadvantage, that of being a good target for artillery fire while stationary, could be offset by quickness of movement from point to point and short stops while hovering.

Detroit's Aerial Contests

THE Aviation Country Club of Detroit announces the sixth annual contest for the Curtiss Marine Flying trophy, first annual contest for the Detroit News Aerial Mail trophy, first annual contest for the Aviation Country Club of Detroit trophy, first annual contest for the Liberty Engine Builders' trophy, and the third annual contest for the Pulitzer trophy. This aviation meet was primarily scheduled for the purpose of holding the third annual Pulitzer Race. However, in order to arouse the widest possible interest in flying and stimulate the development of commercial aviation, the plans have been elaborated to include diversified types of planes. The intention is to attract a varied field of land and water entries to compete for prizes to be awarded on the basis of the best combination of high speed and improved construction without, however, having recourse to complicated rules incapable of being satisfactorily applied.

Event No. 1

The Detroit Aerial Water Derby, including Curtiss Marine Flying Trophy, Monday, September 4th. Cash Prizes: First prize, $1,200; second prize, $600; third prize, $200.

1. The trophy shall be perpetual and competed for annually by seaplanes and flying boats.
2. The contest shall be in the nature of a race either around a closed circuit or from point to point The rules governing the race each year to be drawn up by the Contest Committee of the Aero Club of America.
3. The trophy shall be awarded each year to the aero club represented by the pilot of the winning machine, and this club shall be entitled to the possession of the trophy until one month prior to the next succeeding contest, at which time the trophy shall be returned to the Aero Club of America. The Contest Committee of the Aero Club of America, with the consent of the Board of Governors, has the privilege of conducting each annual contest for the Curtiss Marine Trophy, or of assigning this privilege, under sanction, to any other club or organization.

The Curtiss Marine Trophy

1. CONDITIONS OF CONTEST:

(*a*) Factor of safety—Monoplanes, 6 as loaded for start of race; biplanes, 4 as loaded for start of race.

(*b*) Air speed greater than 70 miles per hour, as loaded for start of race.

(*c*) Visibility and maneuverability (water and air) which in opinion of Contest Committee, Detroit Aviation Society, is not a menace to other contestants or spectators.

2. DISTANCE:

Approximately 160 miles — eight times around a closed course of 20 miles.

3. (*a*) START:

The starting signal will be given at 3 p. m. Planes to be in their allotted places at 2 p. m. Pilots' meeting for the final instructions to be announced later.

(*b*) POSITION AT START:

Planes competing for class and invitation prizes in addition to Curtiss Marine Trophy will be sent away together in a class, the faster classes starting before slower. Competitors for Curtiss Marine Trophy only will be sent away together after the classes.

(*c*) METHOD OF START:

Contestants will be lined up along the shore in shallow water for the start. The starter will assign an assistant starter to each plane who shall raise the signal flags for its pilot, as follows: The starting signal (for motors only), a red flag, will be raised by the chief starter at 2:45 p. m. When the motor on each plane is running, the assistant starter assigned to that plane will raise the red starting flag. When all assistants have raised the red starting flags, but not later than 3 p. m., the starter will raise, in addition to the red starting flag, the white warning flag, which signifies that the getaway signal will be given in ten seconds; each second will be counted by lowering the red flag, the getaway signal being the lowering of both red and white flags. If any contestant has difficulty in starting his motor, his assistant starter will not raise the red starting flag, but, when the chief starter raises the white warning flag, will raise a blue flag, which is a request for a deferred start. Deferred starts shall be granted without penalty, except that no plane will be started after a delay of two hours.

4. THE FINISH:

The finishing time will be taken when each plane flies across the finishing line between the marks defining this line, after having completed the full course, 160 miles.

5. THE WINNER:

Of each first place shall be the pilot which has completed the full course in the shortest elapsed time, and of each second place the second best time, etc., provided the pilot is not disqualified. The Curtiss Marine Trophy will be awarded to the club represented by the pilot and the prize money paid to the entrant of the winning seaplane or flying boat. Agreements between pilots and entrants as to their proportional share of the prize money will be upheld by the Contest Committee, who will pay the prize money in accordance with agreements in writing between pilots and entrants, presented to the Contest Committee prior to the race or within 24 hours after the finish of the race.

6. QUALIFICATIONS:

No seaplane or flying boat may take part in the contest unless it is piloted or commanded by a pilot, who must be on board and who must be furnished with a license issued by the Contest Committee of the Aero Club of America. (F. A. I. Rules, Art. 67.) Every person furnished with pilot's certificate of F. A. I. may obtain license issued optionally by Contest Committee, Aero Club of America. (F. A. I. Rules, Art. 70.) A license will be valid until December 31st of the current year. The Contest Committee, Aero Club of America, may, upon the occasion of any competition or test, issue temporary license as pilot for this one test only to any person whose qualifications it considers sufficient. (F. A. I. Rules, Art. A-28.)

7. DISQUALIFICATIONS:

Any contestant breaking the above rules of the race, or subsequent ones which may be sent out in writing, shall, upon recommendation of the judges, be disqualified.

"Every person organizing or taking part in a sporting event of whatsoever nature is supposed: (1) "To know the present regulations (F. A. I. Rules) thoroughly." (2) "To agree to submit without restriction to the consequences that result therefrom." (F. A. I. Rules, Art. 7.)

8. RULES OF THE RACE:

(*a*) Upon receiving the getaway signal for the start, pilots shall hold a straight course and not cross or attempt to cross in front of the planes on either side.

(*b*) From a standing start contestants will fly around the first four laps of the course, and during laps five, six and seven will be obliged to alight on the water and while running along the surface of the

The Pulitzer Trophy

Digitized by Google

water enter into and pass through, in the proper direction, the water controls which shall be designated by moored markers on both sides.

Note: (There will be only one water control in the shape of a hairpin turn.) The entrance into and exit from this control will be located sufficiently near the turning mark that anything but normal landing speeds or normal taxing speeds will overrun the turning mark and result in loss of time.

(*c*) While within the markers bounding the water controls, the contestants must maintain constant contact between the water and fixed surfaces of the principal flotation gear (wing or tail pontoons, or water rudder, or any other adjustable, movable or flexible attachment is not sufficient contact with the water under this rule).

(*d*) A plane overtaken, both planes being in the air, must hold its altitude and a true course, in order that it may not in any way impede or interfere with the faster overtaking plane.

(*e*) A plane overtaking a slower plane, both planes being in the air, shall never pass or attempt to pass between that plane and any pylon or object used to mark a turning point.

(*f*) Within the water controls, both planes being on the water, the overtaking plane must pass to the right, and all mechanicians of competing planes must look to the rear and warn pilots of an overtaking plane. Pilots of overtaken planes must keep to the left and result in loss of time.

(*g*) The finishing line must be crossed in flight—not on the water—and, after crossing the finishing line, all planes shall continue on their course until they have attained sufficient altitude to enable them to turn and land without crossing the course or finishing line.

(*h*) No contestant shall start before he receives the getaway signal.

(*i*) Pilots shall pass outside all turning points and in plain view of officials stationed at each point, and at an altitude of not more than 250 feet.

Fouling a Mark. "Any contestant who has failed to turn a stake properly may validly continue on the circuit provided he makes a complete turn of the said stake and then continues his trip in the same direction." (F. A. I. Rules, Art. 115.)

(*j*) No contestant shall be permitted to "dope" the fuel with picric acid, ether, or similar highly explosive liquids. Benzol and similar anti-knock fuels may be used.

9. PROTESTS:

No protest shall be considered unless presented in writing to the Contest Committee of Detroit Aviation Society within twenty-four hours after the finish of the race. (F. A. I. Rules, 78, 79, 80.) (Appeals. See F. A. I. Rules, Art 178-179.)

10. NUMBERS:

Each plane shall have a number assigned to it by the Contest Committee, painted on the bottom surface of lower wing and on each side of the fuselage, clear of the wing, in characters as large as possible. It shall have no other numbering over twelve inches in height.

11. ADVERTISEMENTS:

"Competitors are forbidden to display on their apparatus or material any commercial advertisement except the trade-mark of the constructor of the apparatus." (F. A. I. Rules, Art. 89.)

Note: (The word plane as used in these rules means flying boats or seaplanes.)

ADDITIONAL PRIZES:

The (to be announced later) prizes for greatest air speed will be awarded to the contestant who, during the Curtiss Marine Trophy race, completes laps 2, 3 and 4 in the shortest total elapsed time.

The first lap is not included because of the standing start.)

Additional prizes will be awarded for class or invitation races to be announced by the Contest Committee of the Detroit Aviation Society after entries have closed.

(*a*) CLASS RACES:

Four or more planes of the same design and equipped with the same motor shall constitute a class.

CLASS RULE:

Planes eligible for class races are those constructed under the same design and general specifications and not altered to materially change these specifications, nor to prevent the interchange of any corresponding part or parts of any two planes.

Furthermore, should any interchange of corresponding part or parts be directed under this rule, the plane must remain the same after the interchange from the standpoint of design and operation.

EXCEPTIONS:

Stream-lining which does not alter the structure of the part or parts stream-lined.

Motors eligible for class races are determined by the above rule and these exceptions.

1. Stream-lining which does not alter the structure of the part or parts stream-lined.

2. Motors may be equipped with any make or design of propeller, ignition, spark plugs, carburetor, including intake manifold, exhaust manifold, gasoline and oil systems.

(*b*) INVITATION RACES:

The Contest Committee of the Detroit Aviation Society may invite any of the entrants to compete for a special prize.

Event No. 2

Detroit News Aerial Mail Trophy, Thursday, September 14. Cash prizes: First prize, $1,200; second prize, $600; third prize, $200. Race for large-capacity, multi-motored aeroplanes.

1. CONDITIONS OF CONTEST:

(*a*) Factor of safety—Monoplanes, 5 as loaded for start of race; biplanes, 4 as loaded for start of race.

(*b*) Air speed greater than 75 miles per hour.

(*c*) Carrying contracted, specified or advertised loads.

2. DISTANCE:

Approximately 264 miles—four times around a closed course of approximately 66 miles, starting at Selfridge Field, passing over captive balloon located approximately 18 miles away, at approximately 5,000 feet altitude, thence to Aviation Country Club's Field, thence to Packard Field, and then returning to Selfridge Field.

3. (*a*) START:

Starting signal will be given at 11 a. m. Aeroplanes to be on their allotted places on the Field at 10 a. m. Pilots' meeting for final instructions will be announced later.

(*b*) POSITION AT START:

Planes competing for the Detroit News Aerial Mail Trophy will be sent away together in a flight, or series of flights, dependent on the number of entrants and conditions at time of start. However, any entrant will be permitted to start alone after all flights if this request is made to the Contest Committee in writing before Sept. 9th, 1922.

(*c*) METHOD OF START:

The starter will assign an assistant starter to each plane, who shall raise the signal flags to and for its pilot, as follows: The starting signal (for motors only), a red flag, will be raised by the chief starter at 10:45 a. m. When the motor of each plane is running the assistant starter assigned to that plane will raise the red starting flag. When all assistants have raised the red starting flags, but not later than 11 a. m., the starter will raise, in addition to the red starting flag; the white warning flag, which signifies that the getaway signal will be given in ten seconds, giving the mechanics time to draw the blocks from under the wheels. Each second will be counted by lowering the red flag, the getaway signal being the lowering of both red and white flags. If any contestant has difficulty in starting his motor, his assistant starter will not raise the red flag, but, when the chief starter raises the white warning flag, will raise a blue flag, which is a request for a deferred start. Deferred starts shall be granted without penalty, except that no plane will be allowed to start after a delay of one hour. Any plane having once started cannot receive another start; however, it may complete the race, though forced down, provided it can do so before 5 p. m.

4. THE FINISH:

The finishing time will be taken when each plane crosses the finish line between the marks defining this line, after having completed the full course, approximately 264 miles.

5. WINNER:

The winner of the first place shall be the pilot who has completed the full course in the shortest elapsed time, and second place the second best time, etc., provided the pilot is not disqualified.

6. QUALIFICATIONS:

All pilots must hold an Aviator's license issued by the Federation Aeronautique Internationale and duly entered upon the Competitor's Register of the Aero Club of America.

7. RULES OF THE RACE:

(*a*) Pilots must hold a straight course after starting until they have gone the distance to be specified and marked.

(*b*) A plane overtaken must hold its altitude and a true course, in order that it may not in any way impede or interfere with a faster overtaking plane.

(*c*) A plane overtaking a slower plane shall never pass or attempt to pass between that plane and any pylon or captive balloon marking a turning point.

(*d*) Pilots must attain the altitude of the captive balloon each lap, and in passing shall do so to either side in order that the observers in the basket may clearly see the aeroplane's number. Any pilot not having sufficient altitude upon reaching the balloon shall continue to climb, but must make a circle so that when passing the balloon the second time the aeroplane will be headed in the line of flight of the course.

(*e*) All pylons marking turning points must be passed at an altitude not greater than 400 feet.

(*f*) After crossing the finishing line, all planes shall continue on their course until they have attained the altitude of 2,000 feet, then they may turn and return to the field, and land in that part of the field assigned for landing and in so doing shall not cross the course or finish line.

(*g*) Any contestant breaking any of the foregoing rules of the course, or subsequent ones which may be officially announced in writing, shall, upon recommendation of the judges, be disqualified.

8. PROTESTS:

No protest shall be considered unless presented in writing to the Contest Committee of the Detroit Aviation Society within twenty-four hours after the finish of the race.

Digitized by Google

9. NUMBERS:

Each aeroplane shall have a number assigned to it by the Contest Committee, painted on the bottom surface of the lower wing on each side of the fuselage, clear of the wing, in characters as large as possible. It shall have no other numbering or lettering over 12 inches in height.

10. No contestant shall be permitted to "dope" the fuel with picric acid, ether, or similar highly explosive liquids. Benzol and similar anti-knock fuels may be used.

Event No. 3

Aviation Country Club of Detroit Trophy, Thursday, September 14. Cash prizes: First prize, $1,200; second prize, $600; third prize, $200. Race for light commercial aeroplanes.

1. CONDITIONS OF CONTEST:

(*a*) Factor of safety—Monoplanes, 5 as loaded for start of race; biplanes, 4 as loaded for start of race.

(*b*) Air speed greater than 80 miles per hour.

(*c*) Arranged to seat three or more passengers, including pilot, and carrying their capacity load; 160 lbs. of ballast must be carried in place of each passenger omitted.

2. DISTANCE:

Approximately 264 miles—four times around a closed course of approximately 66 miles, starting at Selfridge Field, passing over captive balloon located approximately 18 miles away at approximately 5,000 feet altitude, thence to Aviation Country Club's Field, thence to Packard Field, and then returning to Selfridge Field.

3. (*a*) START:

Starting signal will be given at 12:00 noon. Aeroplanes to be on their allotted place on the Feld at 11:30 a. m. Pilots' meeting for final instructions will be announced later.

(*b*) POSITION AT START:

Planes competing for the Aviation Country Club of Detroit Trophy will be sent away together in a flight, or series of flights, dependent upon the number of entrants and the conditions at the time of start. However, any entrant will be permitted to start alone after all flights if this request is made to the Contest Committee in writing before Sept. 9th, 1922.

(*c*) METHOD OF START:

The starter will assign an assistant starter to each plane, who shall raise the signal flags to and for its pilot as follows: The starting signal (for motors only), a red flag, will be raised by the chief starter at 11:45 a. m. When the motor of each plane is running the assistant starter assigned to that plane will raise the red starting flag. When all assistants have raised the red starting flags, but not later than 12:00 noon, the starter will raise, in addition to the red starting flag, the white warning flag, which signifies that the getaway signal will be given in ten seconds, giving the mechanics time to draw the blocks from under the wheels. Each second will be counted by lowering the red flag, the getaway signal being the lowering of both red and white flags. If any contestant has difficulty in starting his motor, his assistant starter will not raise the red flag, but, when the chief starter raises the white warning flag, will raise a blue flag, which is a request for a deferred start. Deferred starts shall be granted without penalty, except that no plane will be allowed to start after a delay of one hour. Any plane having once started cannot receive another start; however, it may complete the race, though forced down, provided it can do so before 5:30 p. m.

4. THE FINISH:

The finishing time will be taken when each plane crosses the finish line between the marks defining this line, after having completed the full course, approximately 264 miles.

5. WINNER:

The winner of the first place in the race proper, shall be the pilot who has completed the full course in the shortest elapsed time, and second place the second best time, etc., provided the pilot is not disqualified.

6. QUALIFICATIONS:

All pilots must hold an Aviator's license issued by the Federation Aeronautique Internationale and duly entered upon the Competitor's Register of the Aero Club of America.

7. RULES OF THE RACE:

(*a*) Pilots must hold a straight course after starting until they have gone the distance to be specified and marked.

(*b*) A plane overtaken must hold its altitude and a true course, in order that it may not in any way impede or interfere with a faster overtaking plane.

(*c*) A plane overtaking a slower plane shall never pass or attempt to pass between that plane and any pylon or captive balloon marking a turning point.

(*d*) Pilots must attain the altitude of the captive ballon each lap, and in passing shall do so to either side in order that the observers in the basket may clearly see the aeroplane's number. Any pilot not having sufficient altitude upon reaching the balloon shall continue to climb, but must make a circle so that when passing the balloon the second time the aeroplane will be headed in the line of flight of the course.

(*e*) All pylons marking turning points must be passed at an altitude not greater than 500 feet.

(*f*) After crossing the finishing line, all planes shall continue on their course until they have attained the altitude of 2,000 feet, then they may turn and return to the Field, and land in that part of the Field assigned for landing and in so doing shall not cross the course or finish line.

(*g*) Any contestant breaking any of the foregoing rules of the course, or subsequent ones which may be officially announced in writing, shall, upon recommendation of the judges, be disqualified.

8. PROTESTS:

No protest shall be considered unless presented in writing to the Contest Committee of the Detroit Aviation Society, Inc., within twenty-four hours after the finish of the race.

9. NUMBERS:

Each aeroplane shall have a number assigned to it by the Contest Committee, painted on the bottom surface of lower wing on each side of the fuselage, clear of the wing in characters as large as possible. It shall have no other numbering or lettering over 12 inches in height.

10. No contestant shall be permitted to "dope" the fuel with picric acid, ether, or similar highly explosive liquids. Benzol and similar anti-knock fuels may be used.

11. CONDITIONS OF TRIALS:

Trials for operation of self-starter and muffler for planes thus equipped—also the examination for bonuses given for complete accessibility to: Oil, water, gas-filling caps, draining plugs and filtering screens, ignition breakers and distributors, and carburetor adjustments and inspection —will be conducted from August 31st to September 13th, 1922.

12. Any contestant failing to make these trials during this period shall, at the discretion of the Contest Committee, forfeit the rights to the points which he may have gained—even though the trials are made after the race.

13. This trophy and cash prizes are to be awarded on points, given as follows:

(*a*) To the winner of the race proper—600 points. To those finishing within twenty minutes of the winner their pro rata share of points on the basis of a loss of 30 points per minute late.

(*b*) A bonus of 100 points will be given to each aeroplane carrying an operative self-starter.

(*c*) A bonus of 100 points will be given to each aeroplane carrying a muffler which effectively muffles the motor at a height of 1,500 feet, in normal flight.

(*d*) A bonus of 50 points will be given to each aeroplane having complete accessibility to the following: Oil, water, gas-filling caps and drain plugs.

(*e*) A bonus of 100 points will be given to each aeroplane having complete accessibility to the following: Spark plugs, oil and gasoline screens, ignition breakers and distributors, and carburetors in respect to both adjustment and inspection.

In the event of a tie in the scores of two aeroplanes, the aeroplane having received the greatest number of points in the race shall receive an extra point.

Event No. 4

Liberty Engine Builders' Trophy, Friday, September 15. Cash prizes: First prize, $1,200; second prize, $600; third prize, $200. Race for observation type (2-passenger) aeroplanes.

1. CONDITIONS OF CONTEST:

(*a*) Factor for safety—Monoplanes, 5 as loaded for start of race; biplanes, 4 as loaded for start of race.

(*b*) Air speed greater than 90 miles per hour.

(*c*) Carrying U. S. Government specified load for this type of aeroplane.

2. DISTANCE:

Approximately 240 miles—six times around a closed course of approximately 40 miles, starting at Selfridge Field, thence west to captive balloon, thence to Packard Field and returning to Selfridge Field.

3. (*a*) START:

Starting signal will be given at 11:00 a. m. Aeroplanes to be on their allotted places on the Field at 10 a. m. Pilots' meeting for final instructions will be announced later.

(*b*) POSITION AT START:

Planes competing for the Liberty Engine Builders' Trophy will be sent away together in a flight, or series of flights, dependent upon the number of entrants and the conditions at the time of start. However, any entrant will be permitted to start alone after all flights if this request is made to the Contest Committee in writing before Sept. 9th, 1922.

(*c*) METHOD OF START:

The starter shall assign an assistant starter to each plane, who shall raise the signal flags to and for its pilot at follows: The starting signal (for motors only), a red flag, will be raised by the chief starter at 10:45 a. m. When the motor of each plane is running the assistant starter assigned to that plane will raise the red starting flag. When all assistants have raised the red starting flags, but not later than 11:00 a. m., the starter will raise, in addition to the red starting flag, the white warning flag, which signifies that the getaway signal will be given in ten seconds, giving the mechanics time to draw the bricks from under the wheels. Each

Annual Meeting of the Aeronautical Chamber of Commerce

THE annual meeting of the Aeronautical Chamber of Commerce of America, Inc., was held at the executive offices, 501 Fifth Avenue, New York City, July 11. The organization, which was formed the first of the year, with a charter membership of one hundred, reports an increase of nearly 100 per cent in six months. Preparations for flying meets in Chicago in August and Detroit in October were announced.

The following Governors were unanimously re-elected: Grover C. Loening, Loening Aeronautical Engineering Corp.; Charles F. Redden, Aeronautical Airways, Inc.; C. C. Witmer, Airship Manufacturing Co., of America; B. E. Bushnell, Stewart Hartshorn Co.; S. S. Bradley, Manufacturers Aircraft Association, Inc.; Charles H. Colvin, Pioneer Instrument Co.; S. M. Fairchild, Fairchild Aerial Camera Corp.; John M. Larsen, J. L. Aircraft Corp.; Lawrence Sperry, Lawrence Sperry Aircraft Corp.; Frank H. Russell, Curtiss Aeroplane & Motor Corp.; F. B. Rentschler, Wright Aeronautical Corp.

General Manager's Report

Following is the annual report made to the members of the Aeronautical Chamber of Commerce by the General Manager, S. S. Bradley.

Membership

Our organization was formally announced Jan. 1, last, with 100 charter members. In the first six months we have increased our membership to 176, divided as follows: Class A—19; Class B—39; Class C—117. Since the last meeting of the Board of Governors, 7 Class B and 13 Class C members have been added. In addition, full and complete co-operation has been obtained with two important groups in the lighter-than-air field. Among the new members are the following:

Electric Storage Battery Co., Philadelphia, Pa.

Endicott Forging & Mfg. Co., Endicott, N. Y.

Hamilton Aero Mfg. Co., Milwaukee, Wis.

Macwhyte Co., Kenosha, Wis.

Radio Corp. of America, New York.

Standard Oil Co. (Indiana), Chicago, Ill.

Tide Water Oil Sales Corp., New York.

Flying Meets

We have co-operated in holding two flying meets this spring; the first at Garden City on April 30, and the second at Baltimore on May 30. The attendance at the Garden City Meet was conservatively estimated at 20,000; the one at Baltimore, 5,000.

In addition to the above, we have an agreement with the Detroit Aviation Society contemplating our assistance in the management of the races at the flying meet to be given in Detroit next October.

General Contact

Washington: Close liaison has been maintained with official Washington. Representatives of the Chamber held a conference with President Harding on April 13, 1922, at which time the need of aerial law and an aggressive aerial policy was urged. Following this conference the President wrote a most important letter indicating the continuation and extent of his interest in the subject of aviation and our organization. A copy of his letter is attached hereto.

War and Navy Departments: Our contact with the Air Services has followed lines with which our members are familiar, and recently has been particularly active due to the participation of the Departments in the races at Detroit next fall.

For some time we have emphasized upon the War Department the necessity of great care in the release and sale of surplus material. In the past sales of surplus aeronautical material have resulted in a number of fatal accidents, due to the failure of machines in flight. We are therefore gratified to report that such a policy has now been adopted by the Department and that every precaution is being taken, in the absence of air law, to prevent unairworthy material being sold to the public.

We have consistently and persistently advocated recognition on the part of the public and the Government that we must have an aircraft industry before we can have aviation. We have recently seen many evidences of increased acceptance and appreciation of this fact.

During the month of May we completed and submitted to the War Department an extensive aeronautical industrial survey. This survey was based upon a questionnaire originating with the Secretary of War, which we addressed to our members. We have received various acknowledgments from officers in the Air Service and the Office of Secretary of War, advising us that the information thus gathered is greatly appreciated by the Department.

Post Office Department: On January 6, February 21, April 28 and 29, hearings were held by the House Committee on the Post Office and Post Roads on bills introduced by Representatives Steenerson and Kelly proposing authority for air mail contracts. At the request of the Post Office Committee, we sent out a questionnaire to our members and to 100 Chambers of Commerce throughout the United States. A digest of the replies was prepared and submitted by us at the hearings. All of which has been printed in the official report and distributed to our members. Through contact with the office of the Air Mail Division, we have advocated and encouraged the plan to develop night flying of the Air Mail.

Department of Commerce: We have prepared and submitted to the Secretary of Commerce a summary and report of commercial aviation in the United States during the past year. This was submitted to the Secretary of Commerce on April 10, and after being studied by the Department the report was released by Secretary Hoover to the newspapers on June 20. This report also provided material for distribution to Congressional Committees. It has also been very generally helpful as forming the basis for a very large number of constructive editorials in the newspapers throughout the country.

Aerial Legislation

Our work in connection with the Wadsworth Bill, S.3076, has been continuous. In addition to our interview with President Harding, we subsequently had conferences with the Assistant Secretary of Commerce, Mr. Huston; Chairman Winslow of the House Committee on Interstate and Foreign Commerce; Dr. Klein, the head of the Department of Foreign and Domestic Commerce; and Judge Lamb, Solicitor of the Department of Commerce. At Judge Lamb's request we called, at very short notice, a conference of our members at our offices in New York. At this time the entire subject was discussed in detail and it was planned that following this conference final recommendations from the Department of Commerce were to be prepared and submitted to Congress. The advancement of the bill is now delayed on account of a suggestion that has been made to give consideration at this time to the question of the desirability of consolidating all aeronautical activities of the Government in a single department. This is regarded as very unfortunate as it will delay final consideration very greatly.

Trade Association Conferences

On April 13 we participated in the National Trade Association Conferences with Secretary Hoover. A representative of our office was appointed to serve with the National Automobile Chamber of Commerce and the Motor and Accessory Manufacturers' Association, to prepare a foreign trade booklet, to be distributed by the Department of Commerce throughout the world. Copies of this pamphlet have been sent to our members.

On May 16 to 18 we attended meetings of the Chamber of Commerce of the United States. As members of this body, our activities fall within the Department of Transportation and Communication. The manager of this department, J. R. Bibbins, is assisting us in establishing contact with the various local Chambers of Commerce throughout the United States for the purpose of enabling us more effectively to extend our educational work.

We are finding increasing opportunities to extend our work and establish close contact with local commercial organizations throughout the country. Due to the interest aroused by us in the Air Mail hearings, the Merchants' Association of New York City sent a representative to attend the hearings in Washington. Following this, which coincided with a request for data from the Chief of the Air Service, the Merchants' Association decided to appoint an Aeronautical Committee. We had the privilege of conferring with them relative to the personnel of this group. As a result, a member of our organization has been requested by Lewis E. Pierson (president of the Irving National Bank), president of the Merchants' Association, to act as a member of this committee, with a number of very prominent and influential business men whom they have selected for this service.

We have maintained very close relations with the Chambers of Commerce of Boston and Philadelphia. At Philadelphia a representative of our office addressed the representatives of their organization and obtained places on the Aviation Committee for two of our members who are in business in Philadelphia. In Boston we have co-operated with the Chamher of Commerce in their successful effort to secure through the State Legislature an appropriation providing for the establishment of a municipal airport in that city. A letter from this organization, thanking us for our support and co-operation, expresses the conviction that our activity had a very great deal to do with the successful outcome of this movement. We have participated in similar propositions with Chambers of Commerce of Baltimore, with the Aero Club of Illinois, the Chicago Association of Commerce, and other organizations in Burlington, Vt.; Brunswick, Me.; Kansas City, Mo., and Hartford, Conn. A representative of the Chamber addressed the Aero Club of Hartford on this subject of municipal landing fields a few weeks ago.

Except for those members who are in frequent contact with our office, there is probably very insufficient appreciation of the extent to which our offices are used as a meeting place for the exchange of ideas and discussion of general questions affecting the art and industry. There is a constant flow of visitors, the facilities of the library are in constant and increasing demand, questions affecting individual members and the industry as a whole are submitted to us for consideration and advice, with the result that the organization acts as a stabilizing and at the same time stimulating agency, with a constant tendency toward straight thinking and harmonious co-operation throughout the entire field. While this places a great tax upon the personnel of the office, making it at times very difficult to handle the correspondence and other details of routine, we feel that it is very essential that this work be maintained. One tangible result of. this sort of contact that must be apparent is in the quality of the publicity that we are getting. Without the advantages of a clearing house, such as our offices afford, there would be a vast amount of misinformation released and printed. The amount of this sort of material, based upon rumor or suspicion, or hope or expectation, that is arrested and diverted each week is very considerable.

Publicity

Our activities in this field have been carried on along the lines with which members are all familiar. In some respects the work has been expanded. On our initiative arrangements were made for the broadcasting of aeronautical information from the great radio station on Staten Island. This was made possible through the courtesy of the Radio Editor of the New York *Tribune*, Jack Binns. Within the last few weeks we have supplied thirty magazine writers with material and photographs for aeronautical stories. Motion pictures of aeronautical events, which we have either arranged directly or have assisted, are running each week. Aeronautical photographs have been given to the news photo agencies two or three times a week, and at frequent intervals stories of current aeronautical interest are supplied to the Associated Press, the International News, the United Press and all foreign news syndicates with headquarters in New York.

We frequently learn, some time after the event, that various members have participated or had knowledge of important aeronautical news stories, where the opportunity has been missed of utilizing our facilities in securing proper publicity, due to failure to notify us of the event at the time. The members are particularly requested, whenever practicable, to report to this office promptly any event in aviation that appeals to them as being desirable publicity. We cannot promise that each story reported will be featured, but you may be certain that, to the best of our ability and judgment, the matter will receive prompt attention.

Year Book

The Year Book is now ready for distribution. Members are requested to order Year Books promptly if they have not already done so. This year's edition will be particularly valuable due to the Engine Division in the Design Section. This consists of 18 full pages of line drawings of historical and contemporary engines.

Bulletin Service

Every effort is being made by the Chamber to eliminate waste motion, to establish economies and yet maintain our service. The sales, library, Congressional and other memoranda you are familiar with. To meet a real demand, especially from the Class C members, and also to provide a medium for the dissemination of data of general interest to all members, a new series of bulletins has been established to be known as "Information." This bulletin, the first of which was issued in June, will be produced the first of each month and sent to the entire membership. This is also used for publicity purposes.

New Projects

Detroit Races: We have an agreement with the Detroit Aviation Society to co-operate with them in the management of the races at the time of the contest for the Pulitzer Trophy in October of this year. A representative of our office will attend to the details of management of the races beginning July 20 and ending October 20, and this office will, either from New York or Detroit, handle and direct all publicity.

Chicago Meet: Through the incorporation, a few weeks ago, of the Chicago Aeronautical Bureau, the situation in Chicago crystallized into

The 18-Ton Parseval Semi-Rigid Airship "PL27"

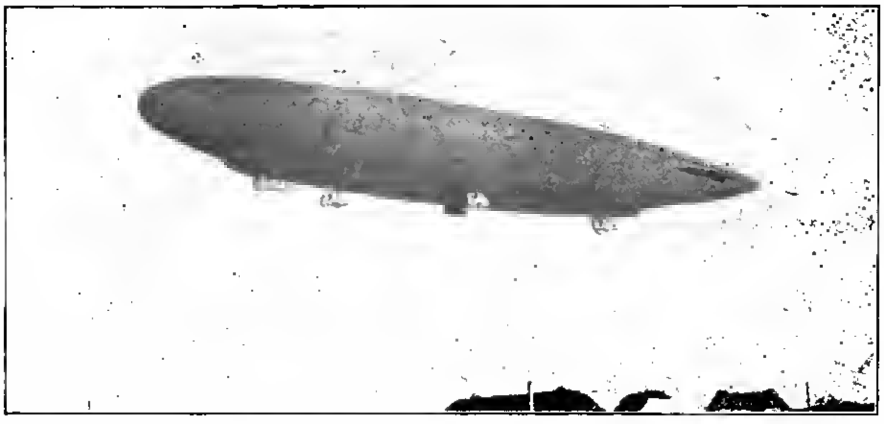
ALTHOUGH built as long ago as 1916, there are several reasons why the Parseval type "PL27," designed and built by the Luftfahrzeug-Gesellschaft of Bitterfeld, is of sufficient interest to merit a fairly detailed description at the present time. In the first place, the airship was one of the largest semi-rigids ever built, being only very slightly smaller than the ill-fated "Roma," purchased by America from Italy some time ago. Secondly, her design was one representing a considerable departure from previous German non-rigid practice, approaching, in fact, more to the Italian than to previous German types. In spite of the accident to the "Roma," this type of airship is thought by many to have a very considerable future before it, and it is open to discussion whether the world, led by Germany, was right in deciding in favor of the rigid type of ship. In Germany at the present time, there is a strong opinion that the limits in non-rigid and semi-rigid airships have in no way been reached, and certainly one could enumerate several advantages which these types possess as against the rigid. One very important item is that of cost, and in this respect the non-rigid, and, to a somewhat smaller extent perhaps, the semi-rigid compares very favorably indeed with the rigid. The very expensive Duralumin framework is avoided, which at once means a great saving. Col. Cave-Browne-Cave, one of our soundest, and certainly our most persistent and eloquent advocate of the non-rigid airship, stated in one of his admirable lectures before the Royal Aeronautical Society that, according to his calculations, six non-rigids, each of 500,000 cubic feet capacity, could be built for the price of one rigid of 2,000,000 cubic feet capacity. In other words, with the non-rigid, we should get an extra million cubic feet capacity for the same money.

Then there is the question of useful load. Here again Col. Cave-Browne-Cave indicated that a greater percentage of useful lift is obtained in the non-rigid than in the rigid, owing chiefly to the absence of the hull structure. Thus the point where the structure weight is no more than 50 per cent of the total lift is reached in the non-rigid with the half-million cubic feet ship, whereas in the rigid it is not attained until one comes to sizes of about two million cubic feet. It would, therefore, appear that we may have been on the wrong track in pinning our faith almost exclusively to the rigid type. With things as they are at present, the question of the purchase, running and upkeep of a rigid is a big item. It is, at least, open to doubt whether we should not be better advised in making a start on airship services with types other than the rigid. As regards safety, there is probably little to choose between the types, and the non-rigid, apart from the advantages already outlined, has another in that, when not in use, it can be deflated and stored away in the corner of a shed. A rigid airship occupies as much space when deflated as it does when inflated. Furthermore, in the case of a forced landing, the non-rigid, and the semi-rigid which has its keel built in sections, can be packed up and sent home. The rigid, if it should be forced down from any cause, would almost certainly have to be written off as a total loss.

There is a great deal more which could be said about non-rigid and semi-rigid airships in general, but sufficient has, we think, been said to indicate that, as it has now been proved that these types need not be restricted to small airships, this class of airship deserves more consideration, from a commercial aviation point of view, than it has received in the past.

The Parseval "PL27" has an over-all length of 157 meters (515 ft.), a maximum diameter of 19.6 meters (64 ft. 4 ins.), a greatest circumference of 61.55 meters (202 ft.) and a height of 26.5 meters (87 ft.). Its cubic capacity is 31,300 cubic meters (1,104,000 cubic ft.) and the disposable lift is approximately 18,000 kilograms (nearly 18 tons). Assuming a lift of 65 lbs. 1,000 cubic ft. of hydrogen, the total lift would be approximately 32 tons, so that the disposable lift is 56 per cent of the gross lift, which is considerably better than the figure of 50 per cent given by Col. Cave-Browne-Cave for a 500,000 cubic ft. ship. The allocation of this 18 tons of lift would, of course, depend upon the purpose for which the airship was intended. For a very long flight a great proportion of it would be taken up by the fuel. For shorter distances the lift which could be set aside for paying load would increase. If the route on which such a ship was used were to be divided into stages of approximately 1,000 miles each, the "PL27" could carry a crew of seven, sufficient fuel to leave a safe margin, and, in addition, have accommodation for about twenty-five passengers. It will thus be seen that, as regards earning capacity, the "PL27" should be a very useful craft as a passenger and mail ship, especially as her cruising speed is said to be about 60 m.p.h. It is estimated that these airships could be built in England for not more than £30,000 each, and if built in batches, the cost should be even lower. Thus, by reducing the length of the stages flown to approximately 1,000 miles, a much more economical service should be possible than if large rigids, capable of doing the London-Cairo trip without landing, were employed. In this way, the time for the journey to Australia, for instance, would be somewhat increased, but, on the other hand, it is at least conceivable that a greater revenue would be forthcoming, as it should be easier to fill up the ships with passengers for shorter distances over portions of the route.

As regards the design and construction of the Parseval "PL27," this ship is, to some extent, based upon the Italian designs in which there is a keel structure running the greater part of the length of the airship, and to which are attached some of the heavier local loads such as petrol and water tanks, central engine



The 18-Ton Parseval Semi-Rigid Airship "PL27"

Digitized by Google

View of the forward position of the airship, showing the control car

cars, etc. This structure is so designed that its parts form, as it were, the links of a chain. In the "PL27" the keel, which is about 330 ft. long, is divided into fifty-two separate cells or units, the whole being so designed that the keel can resist longitudinal loads, but not bending moments, owing to the manner of joining the cells to each other. The keel is built up of a tubular framework consisting of four main longitudinals, struts and wire bracing.

Three of the cars, the control car and the front and rear engine cars, are attached direct to the keel, while the two side engine cars are slung by cables from the envelope, and steadied laterally by struts to the keel. The attachment of the keel to the envelope is by rigging wires and fabric. As already mentioned, the keel serves to support, in addition to the three cars, the petrol tanks and water ballast bags.

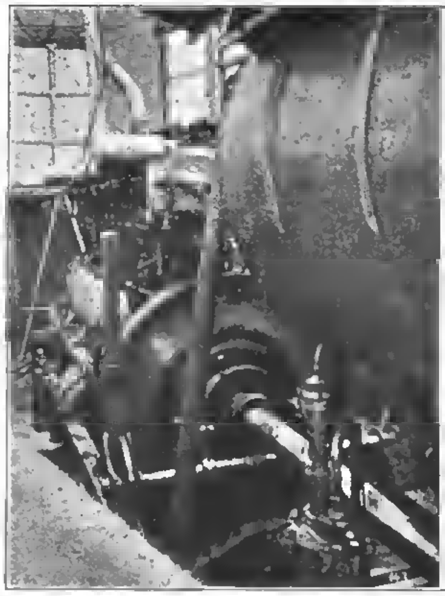
The latter are of two kinds. One is known as "trouser" (*Hosen*) bags, and are emptied singly by means of a ripping line from the control car. The other kind has valves, and is emptied, also from the control car, two at a time. All the bags are of 200 kilogs. (440 lbs.) capacity. The "trouser" bags are mounted four forward and two aft. The ordinary bags, of which there are thirty-six, are distributed along the keel, the valves of every two bags being connected to one control line, so that with these 880 lbs. of water is discharged at a time. The total amount of water ballast carried is thus 8,400 kilogs. (18,500 lbs.).

The petrol tanks are hung in the keel, as shown in one of the accompanying photographs. Normally, thirty petrol tanks are carried, twenty-six main tanks and four gravity tanks, one for each engine. The capacity of each tank is 200 kilogs. (440 lbs.), so that normally the total petrol capacity is 13,200 lbs. (nearly 2,000 gals.). Provision is, however, made for slinging another ten petrol tanks in the keel, bringing the petrol capacity up to 8,000 kilogs. (17,600 lbs., or about 2,500 gals.) if long journeys are contemplated. The list available for paying load is then, of course, correspondingly decreased. In fact, by the time one had counted in a crew of about ten, with their provisions, there would be little more load available.

As regards the placing of the petrol tanks in the keel, they are arranged in three groups, corresponding to the arrangement of the engine cars. The forward group, feeding the front engine, consists of six main tanks and one gravity tank. A similar number and arrangement feed the aft car, while the central group, which supplies the two wing engines, consists of fourteen main and two gravity tanks. All the tanks are arranged for easy slipping in case of emergency.

The arrangement of the cars will be understood from a reference to the accompanying photograph of the airship in flight. The control car is placed right forward. A short distance aft of this is the forward engine car, under the keel of the airship. Approximately half-way along the length of the ship are the two wing engine cars, some distance out from the center line, and finally near the rear end of the keel is the aft engine car. Each of the engine cars contains one 240 h.p. Maybach engine, driving pusher screws through reduction gearing and clutches. The engines are mounted with their crankshafts about 10 ins. above the floor of the car, and the lower part of the crank-case can be reached by removing a loose floor plate. The transmission includes a reverse, two wheels being in mesh for forward and three for reverse. The reduction is such that, although the engines run at 1,400 r.p.m. at full power, the propellers run at 180 r.p.m. only. Their diameter is 14 ft. 9 ins. A blower, or fan, placed in the stern of the car, is driven at a speed of 1,850 r.p.m., by means of a silent chain, and delivers 2½ cubic meters (88 cubic ft.) of air per sec., at 100 mm. of water. The engine cars have a length of 6 meters (19 ft. 8 ins.), a maximum width of 1.8 meters (5 ft. 11 ins.), and a height of 1.6 meters (5 ft. 3 ins.).

The control car is 9 meters (29 ft. 6 ins.) long, 2 meters wide (6 ft. 7 ins.), and 2 meters high. It is divided into three compartments, of which the forward one is the control cabin, and the aft one the wireless compartment. From the central compartment access to the keel is gained via an automatically closing trap door, and a shaft leads through the hull to a platform on the top of the envelope. In the control cabin the rudder control wheel is placed forward and slightly over towards the starboard side. The elevator control



Views inside the port engine car. On the left, the engine, clutch, and air compressor; on the right, close-up view of the engine and blower

Digitized by Google

wheel is placed on the port side. The control cabin is, of course, provided with a number of instruments, as well as with the controls for gas and air valves, etc.

The hull or envelope of the "PL-27" is made of three-ply fabric, of which the inner and outer layers run longitudinally, while the middle layer is placed at an angle of 45 degrees. The tearing strength of the fabric is stated to be 2,000 kilogs. (4,499 lbs.) per meter width. In addition to this strong fabric, the hull is strengthened by so-called trajectory bands. These are bands of webbing, about 2 ins. wide, stuck to the envelope fabric and covered with water-tight cover strips. The use of these bands constitutes, we believe, a Luftfahrzeug-Gesellschaft Patent. The tearing strength of these bands is 1,320 lbs.

The gas space is divided by three fabric bulkheads, into four compartments, of which the forward and aft have a capacity of 6,260 cubic meters (220,500 cubic ft.) each, while the other two have a capacity of 9,390 cubic meters (331,500 cubic ft.) each. The fabric bulkheads are reinforced with wehhing and are capable of carrying a difference in pressure between their two sides. If, for any reason, it should be necessary to equalize the pressure in two adjoining gas compartments, this can be accomplished by a hose which is normally kept closed by being tied up, but which can be opened by the crew.

Each gas compartment is provided with an air bag or ballonet, which when completely filled occupies 52 per cent. of the gas compartment volume. Thus, the capacity of the fore and aft ballonets is 3,250 cubic metres (115,000 cubic ft.) each, and that of the second and third ballonets 5,000 cuhic metres (176,500 cubic ft.) The ballonets consist of two portions, the lower of which, attached to the envelope, is made from two-ply fabric, of a tearing strength of 1,200 kilogs. per metre width, while the upper part is in a single thickness and has a strength of 900 kilogs. (2,000 lbs.) per metre width.

Each of the gas compartments is provided with two gas valves, placed in shafts and discharging through the top of the envelope. The openings on the top of the envelope are covered with fabric hoods. Each ballonet has two air valves, built into the keel, and having discharge pipes leading into the open. In addition, each ballonet has an inlet valve of the flap type, serving to admit air from the fans. The four flap valves communicate with a common pipe or hose, into which all four blowers discharge. Each hallonet has also a pressure regulator (automatic) which ensures that there is always an excess of pressure of 25 mm. of water. Should the pressure fall to 23 mm., the regulator opens the inlet valve, which communicates with the common pipe from the blowers and keeps it open until the old pressure has been established, when the valve is closed. If the pressure rises to 27 mm., the pressure regulator opens either the air valves of the ballonet or the gas valves of the gas compartment, or both, according to the setting of the switches in the control car. The actual operation of pulling the air or gas valve cords is carried out by the automatic regulator, although when required, as, for instance, in landing, members of the crew can operate the valves direct, without the action of the regulator.

Two views of the port engine car. On the right can be seen the struts which brace the car to the keel structure

The tail planes are so attached by struts, etc., that they cannot be pressed into the envelope. They are designed for interchangeability, the fins and tail planes being identical. The elevators are, however, different in shape and size from the rudders.

Altogether, the Parseval "PL27" is a very interesting airship, and it has proved that it is possible to design even quite a large ship without necessitating a change over to rigid construction. It is confidently expected by the *Luftfahrzeug-Gesellschaft* that, if desired, even larger ships can be built on this principle, hut even taking the "PL27" as she existed in 1916, the type should have a considerable sphere of nsefulness at the present time, and the type has the advantage of having been tried out to the satisfaction of the designers, behaving well during maneuvering, and showing a good turn of speed. It may be expected that when Germany is once more free to develop, without the present restrictions, more will be heard of airships of this type, and we should not be surprised to hear of regular services heing established hetween Berlin and London, which cities are sufficiently far apart to afford a considerable saving in time by traveling by air, and yet not so far as to necessitate the use of rigid airships.

Reserve Officers Receive Instruction at Mitchel Field

Twelve reserve officers reported at Mitchel Field, L. I., New York, in a body on Saturday, May 13th, for flying and for instruction in installation of radio equipment on aeroplanes. Major Harrison H. C. Richards, Air Service, on duty with the Reserve, was in charge of the party. All of these officers were given flights, which took up largely refresher flying instruction and practice landings. To date, no reserve officer who reported at this station with proper credentials, authorizing participation in aerial flights, has been refused an aeroplane.

The Army pilots charged with the duty of giving this refresher instruction to the many reserve officers reporting at Mitchel Field report that these officers get hack into shape very rapidly.

The Air Service Mechanics' School

At the present time there are 550 students undergoing the various courses of instruction at the Air Service Mechanics' School at Chanute Field, Rantoul, Ill. This leaves an approximate number of 110 men awaiting instruction. These men will be entered within six weeks. The entrance of this number of men will exhaust the last of the men enlisted in the recruiting drive some six months ago. There are now sixteen courses of instruction in active operation.

Photographic Missions Completed

Lieutenants Robert E. Selff and Wm. C. Goldsborough, have completed their seven thousand mile photographic mission, having photographed all available landing fields in Northern California and Nevada. They landed at Crissy Field while the Flying Circus was in full blast, and were heartily greeted hy their flying "Buddies".

On Friday, May 26th, Captains W. A. Bevan and R. G. Irwin and Lieutenants J. P. Richter and C. R. Weber landed at Crissey Field, after completing their mission of photographing the landing fields of Southern California and Nevada. An 18,000 ft. high sandstorm was encountered hy them on their flight across Death Valley, which, it is believed, is the reason for the copper tipping on their propellers being so shiny.

The Handasyde Type H.2 Monoplane

THE FUSELAGE

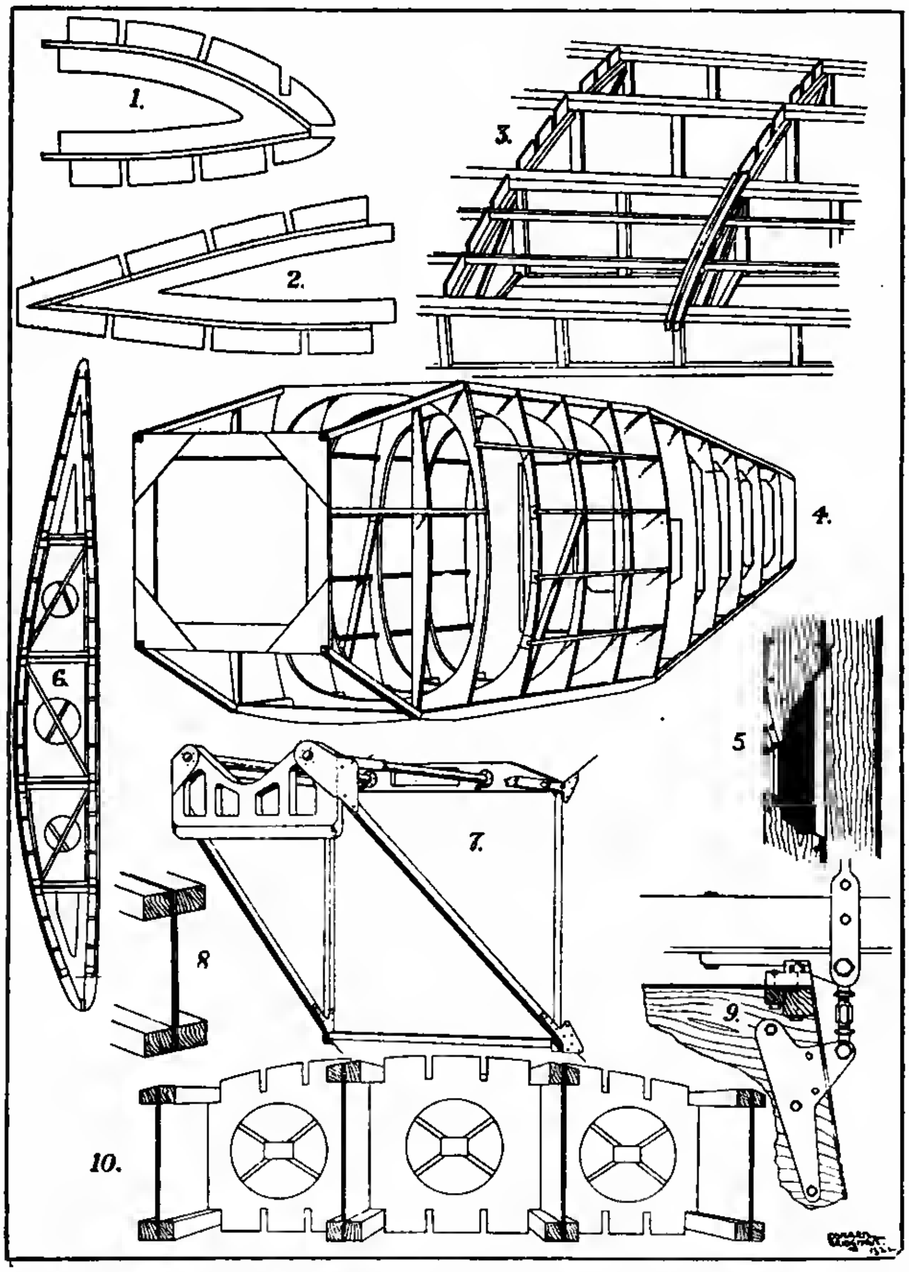
The fuselage—which is apparently the least novel part of the machine—appears to be of the normal three-ply covered type now so widely in use. Actually it has a number of novel features, and is not quite so commonplace as it might at first appear. It is really of the braced longeron and strut type, the bracing being performed by the ply wood skin. The "struts" are in the form of hoops, which also act as formers.

This fuselage is built in two parts, the forward one an engine-carrying nose, and the after part, which contains cabin, etc., and carries the tail. The main fuselage body is built on four longerons—each one of which is in three straight lengths. The forward length, of spruce, covers the space occupied by the pilot's cockpit. Over this space the longerons diverge rapidly in side elevation from front to rear. There follows a second straight length, corresponding to the passenger cabin, which is also of spruce. Over this space the four longerons are parallel. From the rear of the cabin to the tail longerons are of ash. The top longerons over this section slope down very slightly towards the tail, the lower longerons sweep up very considerably.

Joints between these longeron sections are of the simple fishplate type, and are covered by three-ply skin—so that the main body of the fuselage is not a dismountable structure.

The front frame of the forward section consists of four spruce members, with three-ply cornerpieces. There is an intermediate set of four spruce struts and thereafter follows the hoop structure of the cabin.

The hoops—which are in effect the fuselage struts, in this cabin portion—are of box section. The inner member of each box is a bent hoop made of ash in two plies. The outer members are of spruce, and the sides of the box are formed by three-ply. The whole structures are glued and screwed together.



Details of the Handasyde Monoplane.—(1) the nose and (2) the tail of one rib former. (3) Part of the main wing structure, showing the four main spars and two ribs. The left band rib is without capping strips. The through stringers are in place between the two nearest spars, and the capping strips are in place over the first section of the rigbt-hand rib. (4) The skeleton of a fuselage seen from the front. (5) Section of one of the fuselage main hoops, showing construction. (6) Elevation of a complete rib (compare figs. 1, 2, 3, 4). (7) The nose of the fuselage. (6) Diagram of wing spar structure. (9) Attachment of a wing spar to the fuselage. (10) End view of a wing root, showing spars and four sections of the formers for a rib

The after "hoop" at the cabin end has the three-ply sides of the box extended inwards, and a door-frame worked into the structure, thus partitioning the cabin from a mail compartment which is immediately aft of it.

Aft of the cabin, the struts are built up of spruce only, but are in general of the same type of shape as the cabin hoops. The first beyond the cabin is three-ply covered to form the bulkhead of the goods space, but is fitted with a sliding door so that one may crawl into the after part of the fuselage for inspection. At the rear end of the body there is another solid bulkhead just forward of the front spar of the tail plane.

Over and above the four main longerons there are numerous stringers of spruce from the front of the cabin to the tail. In the cabin length these stringers are continuous, except for the necessary stoppage at the door, which is arranged between the first two of the cabin frames. They are let into the outer spruce members of the hoops. Over the after part these stringers are stopped at each frame, and serve only to support the outer skin. The skin of three-ply is screwed to all frames, longerons, and stringers. Joints in the three-ploy are made by butting the two sheets, applying a "fishplate" of three-ply about 4 inches wide on the inside only, and riveting through from skin to "fishplate" with hollow rivets of about 3/16 diameter pitched about 3 inches apart.

The general appearance of a fuselage framework uncovered is shown in one sketch. A succeeding sketch shows the engine-carrying nose which is attached to the main body. This nose consists of two ash members on each side, which meet at a forward cross member of five-ply spruce. The engine bearer tubes run from the front cross member to the upper cross member of the bulkhead in front of the pilot. This nose does not form a

Digitized by Google

detachable engine mounting, because the after support for the engine bearer is part of the main fuselage structure. The nose is however removable after taking out engine and bearers, and this appreciably simplifies packing up the machine for transport.

WING STRUCTURE

The structure of the wings is the most interesting part of this machine. The machine is of the cantilever monoplane type, with the wing entirely above the fuselage. The whole conception of these wings is unusual. They are of the multi-spar type, with a wooden covering, and apart from the joints between the wings and the body, the two halves of the wings, and aileron hinges and control mechanism the only metal parts employed are screws.

The wings are heavily tapered, both in plan and in section, from root to tip. The leading edge sweeps back slightly, the trailing-edge very pronouncedly. The section is an unusual one. The top surface is of the usual type, with its maximum camber in the region of 1/3 the chord from the leading edge. The lower surface is practically flat over the spars, but slopes down sharply from the leading edge to the front spar, and somewhat less sharply up from the rear spar to the trailing edge. The section therefore is biconvex. The four spars, which are spaced at approximately equal intervals across the chord, are all of the H section built up, with top and bottom flanges of spruce in two halves, and a web of spruce two-ply, which web is covered with glued on fabric. The flanges are glued and screwed to the webs.

The ribs are formed of three-ply built in sections which fit into the recesses in the spars. They are stiffened with spruce members glued and screwed to them, roughly parallel to the wing surfaces, but considerably inside those surfaces. The outer edges of these rib webs are notched between spars, the through-going spruce longerons are run through the notches. There are two of these stringers between each spar. Over the stringers is applied a set of continuous spruce laths, which form the rib flanges proper. These are screwed to each spar and stringer. The covering consists of strips of spruce, corrugated internally, which are laid on parallel to and flush with the rib flanges, and are also screwed to each stringer and spar. This spruce skin serves the purpose of drag bracing, and also as the top and bottom flanges of the composite girder formed by the whole structure. The leading edge and the trailing edge are formed by three-ply formers similar to those between spars, which are supported by the through rib flanges. These are also provided with longitudinal stringers running right through. The leading edge proper is formed of three-ply bent to trough section, screwed to the leading stringers, which are of extra heavy section. The trailing edge is of solid spruce.

The details of this very novel wing structure are well shown in some of the accompanying sketches.

The wings are built in two sections, which join on the centre line of the machine. Owing to the fact that except in the case of the front spar, all spars meet at an angle, it has required form of joint. A sketch shows how some ingenuity to obtain a simple the difficulty has been overcome.

The wings rest on the top rail of the fuselage over the cabin. An aluminum block is fitted beneath each spar, and this block carries at its outer end a downward projection which registers on the outside of a mating block of the same material on the longeron. This block on the longeron is fitted with two upwardly projecting tongues, one of which registers on each side of the block on the spars. Therefore when each set of these blocks is properly engaged, the wing is accurately located both laterally and longitudinally in reference to the fuselage.

The lift load from the spar is taken to the main fuselage structure through one right- and left-hand screw adjuster—generally of the nature of the ordinary wire strainer, which is coupled at the top to a strap surrounding the spar and at its bottom to a lug attached to one of the main fuselage frames.

From this description and from the sketches it will be realized that this machine has many features of great novelty and interest. The type of construction is necessarily somewhat expensive at the outset, but as soon as the necessary jigs are set up repetition should be extremely cheap. The absence of complicated metal fittings allows the machine to be built by any competent staff of woodworkers, and if in fact the type proves to be free from trouble due to warping of the timber, it may prove to be a serious rival to metal structures in the future.

The Aeraplane.

A New Czecho-Slovak Commercial Biplane

IN the first commercial aeroplane to be designed and constructed in Czecho-Slovakia this re-born country has demonstrated that, in spite of the fact that up to a few years ago its aviation industry was conspicuous for its absence, it is already capable of taking its place amongst the foremost aircraft constructing nations. This new commercial machine has just been turned out from the works of the Aero Aircraft Factory of Prague, whose designers, MM. Husnik and Vlasák, are to be congratulated in having produced a machine the general lines of which at once strike one as being both practical and pleasing to the eye.

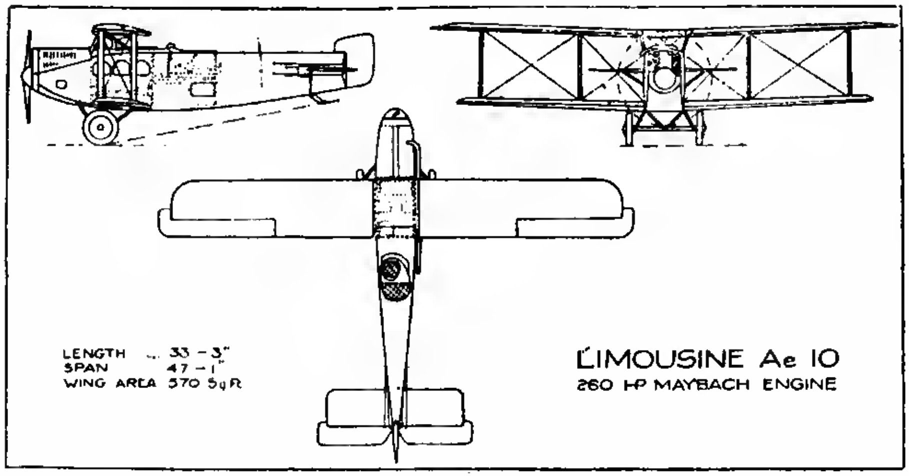
The Limousine Ae 10 was designed to meet the needs of the growing demand for aerial intercourse with neighboring countries, the Republic being determined to take an active part in the various aerial services running, and to be run, to and from Czecho-Slovakia. It is a tractor biplane, with a deep *fuselage* of good streamline form. The engine, a 260 h.p. Mayhach Mb. IVa, is mounted in the nose and drives a 10 ft. 3 in. tractor screw. The radiator is mounted behind the latter, and has been found to give very satisfactory results, causing little resistance.

Behind the engine is an enclosed cabin accommodating three or five passengers, and separated from the engine compartment by a double metal-covered partition as a precaution against fire. The cabin is very roomy, well upholstered, and has double walls, ceiling and flooring, giving an exceedingly strong construction; it is also isolated and noise-proof, and so adds to the safety and comfort of the passengers. Three windows, glazed with Triplex, on each side of the cabin give a good range of vision, whilst the rear window may be used as a direct communication between the cabin and the pilot—conversationally, of course.

Access to the cabin is by means of a door on the right-hand side of the cabin. In the cabin are three comfortable seats, and two tables which are upholstered underneath, so that they can be tilted up and used as seats when two extra passengers are carried. At the rear of the cabin is a space for luggage, measuring 5 ft. 10 in. by 3 ft. by 2 ft. Above this is the pilot's cockpit, just behind the main planes, from which an excellent view in all directions is obtained. Provision is also made for the accommodation of a navigator, who has a seat just behind the pilot, and both can easily change places if desired. A fire extinguisher, in direct communication with the engine and carburetor, is also located in this cockpit.

The main planes are in five sections, the lower in two attached direct to the *fuselage,* and two upper attached to a small center section. They are set at a dihedral angle, but no sweep-back, and the top plane has a very

Digitized by Google



slight overhang. Balanced *ailerons* are fitted to the top plane only. The main petrol tank is carried in the top center section, whence the petrol is led by gravity through a single pipe, *via* a filter, direct to the carhuretor. The petrol system is thus of the simplest form possible. The tank is filled hy means of a special pump, and the petrol passes through a filter before entering the tank.

The tail planes are of tubular steel construction, fabric covered, and consist of an adjustable rectangular horizontal stabilizer, mounted between the upper and lower *longerons* just above the line of thrust, two balanced elevators hinged to the stabilizer, and a balanced rudder. No vertical fin is fitted, as the flat sides of the *fuselage*, which tapers to a deep vertical knife-edge, renders this unnecessary. The controls are of the conventional type —elevator and *aileron* column, and rudder har.

Special attention has been given to the undercarriage, as it was realized that many of the accidents are caused by faulty landing gear. The two wheels are of large diameter—960 mm.—with the object of enabling the machine to land on very soft and uneven ground. They are located well forward, which has the effect of giving a quick pull up. The wheels are mounted on a divided axle, with rubber shock absorbers, which is carried by twelve steel struts, having six points of attachment to the *fuselage*. These struts are arranged in three pairs of "M's, when viewed from the front, as indicated in the accompanying general arrangement drawings. Landing shocks are thus well distributed over the *fuselage;* in places the factor of safety is about 12, both in the landing chassis and cabin. Throughout the machine double wiring is employed.

The principal characteristics of the Limousine Ae-10 are:

Span	47 ft. 1 in.
Chord	5 ft. 9 in.
Length	33 ft. 3 in.
Height	11 ft. 8 in.
Area of main planes	570 sq. ft.
Useful load (3 pass.)	1,650 lbs.
Weight, fully laden	1,620 lbs.
Weight/sq. ft.	8.2 lbs.
Weight/h.p.	17.7 lbs.
Speed	93 m.h.p.
Duration	4 hours
Engine	260 h.p. Rayhach

—*Flight.*

Weather Forecasts

In its desire to have its forecasts, warnings, and information made of the greatest possible benefit to aviation and aviation interests, the United States Weather Bureau has arranged a plan of cooperation with the Chief of Air Service, U. S. Army, by which it is hoped closer contact may be established between its aviators and Weather Bureau officials in the field.

The plans of this cooperation have been announced by the Chief of Air Service to all commanding officers of Air Service fields in a letter which describes the arrangement.

In this letter the Weather Bureau requests that, in order that the personnel of the Army Air Service and the Weather Bureau may become personally acquainted and by so doing be able to discuss the possibilities and limitations of their respective services, the pilots at the various Air Service fields in their regular training fly to the various Weather Bureau stations shown on the Weather Bureau map which are within a radius of 300 miles from such fields, become acquainted with the personnel at such stations, discuss the problems of the two services, and arrange a system of cooperation. The prevailing weather conditions of the particular section of the country involved should be discussed as bearing upon the work of the Air Service. On these trips the pilots should make notes of the terrain flown over and the landing facilities en route and at the destination.

The Weather Bureau deems it advisable that lectures on the general work of that Bureau, the weather conditions of the particular country where Air Service fields are located, and meteorological subjects pertinent to aviation should be delivered to the Air Service personnel, and the Chief of the Weather Bureau invites applications from Air Service Fields with the purpose in view of making arrangements for the delivery of such lectures.

Aviation forecasts for the six aviation forecast zones of the United States covering the country east of the Mississippi River are broadcasted by Radio from the Naval Radio Station at Arlington at 10:30 a. m. (5950 CW) and at 10:00 p. m. (2650 CW). The Weather Bureau requests that arrangements be made to have radio operators on duty at Air Service stations within these zones receive these forecasts. The night forecast will cover weather conditions in the zone until noon of the following day, whereas the morning forecast will cover weather conditions from noon until midnight.

The Washington *Post* and the Washington *Herald* publish each morning a special forecast furnished them by the Weather Bureau for routes from Washington, D. C., to Norfolk, Va., and from Washington, D. C., to New York City, and arrangements will soon be made for a similar forecast for the route from Washington, D. C. to Dayton, Ohio.

Request for information on weather conditions from Air Service fields, whether made by telegraph or telephone, are to be without expense to the Weather Bureau; but any aviator of the Army who has made a landing at a point not near an Air Service field is permitted to send a prepaid telegram to a Weather Bureau office for the purpose of obtaining the latest forecasts and information as to prevailing or conditions. Weather Bureau officials receiving such messages are instructed to reply promptly, giving the best possible information in answer thereto and transfer same to the sender at the expense of the Weather Bureau, such reply messages to be checked "Paid WEA."

AERIAL AGE

PUBLISHED MONTHLY

Copyright, August, 1922, by THE AERIAL AGE CO., INC.
5942 Grand Central Terminal, New York

Vol. XV AUGUST, 1922 No. 16

Shall Britannia Rule the Air?

A PROGRAM of development of aviation which would give to Great Britain as complete a domination of the air as was her domination of the sea prior to the world war is now under consideration and apparently likely of adoption as a definite permanent policy of the British government. Dispatches from London report that the British press is flooded with aviation propaganda preparing the people for huge government expenditures necessary to float an air fleet, subsidize private commercial lines, aid plane and motor manufacturers, continue experimentation, and train and maintain pilots, observers, and mechanicians.

That is a natural development of the British character and of Britain's many years of experience in the government of an empire stretching around the world. The British government and people have long realized that only through the maintenance of the world's greatest navy could they have full assurance that the lines of communication and trade between the widely separated parts of the empire would be kept open and maintained in any emergency. A dominant navy meant life of the empire.

The rapid rise of the United States as a sea power in the closing years of the world war brought Britain face to face with the necessity of sacrificing this position. The American program threatened to outbuild Britain. The economic condition of Britain was such that it could hardly hope to compete. At the same time lessons of the war and experiments in the sinking of battleships by aeroplanes which followed the war cast considerable doubt upon the ultimate value of battleships as opposed to aeroplanes. There was no certain conclusion that a $40,000,000 battleship would be helpless before a $10,000 aeroplane, but there was a doubt.

The odds were too great to bet against. That, probably as much as anything, was a leading factor in the Washington decision for the limitation of capital ships. But that did not change the British belief in the necessity of remaining dominant among the nations if possible. The great aviation program outlined is a direct result of that conviction. It shows the way for America.

Our dominions extend from the Philippines to the Virgin islands, and from Alaska to Porto Rico. Our responsibilities extend even further—definitely to the tip of South America. We must be in a position to defend and maintain this territory and these responsibilities. If England has, through its envoys, accepted the 5-5-3 naval agreement only with the intention of stopping development on the sea to begin it in the air, our program should be clear before us.

Every British aeroplane should be matched by an American aeroplane. Every British dirigible should be matched by an American dirigible. Every British hangar and landing field and supply station and experimental station should be matched by its equivalent in American territory. Every British expert in the development or operation of flying machines and in aerial warfare or commerce should be matched by an American as good, or better. And then we should have a few extra.

We do not expert to have war with Britain. In fact we intend not to have war. But in any emergency which may arise we should be competent to emerge the victor. We have voluntarily given up what would have been a campaign of superiority on the sea. Thereby we have saved hundreds of million of dollars without additional risk. But that risk comes if we submit to a position of inferiority in the air. No premium is too great to pay for insurance against such a risk.—*Editorial in Chicago Tribune.*

Army Air Service Promotion

THE death during the flight of two officers of the Army air service—those of Captain Thomas H. Shea, Jr., and Lieutenant R. E. O'Hanly—has again called attention to a situation in that branch that is in dire need of correction. Such casualties are of so frequent occurrence as to sustain a record of eight per cent of flying officers who are killed every year. Vacancies created in this way are not filled by the promotion of air service officers, but by transfers to the air service of officers of other branches of the Army. The air service is unfortunate in the position on the promotion list of its junior officers, who, because of their long period of training during the war, now find themselves segregated near the bottom of the single list. Their seniors are in many cases younger in age and only longer in service by a few weeks or months, a circumstance that determines relative place on the promotion list, by virtue of the fact that the average period of training in other arms was about three months as compared with the air service training period of about nine months. The result has been that not only has the commissioning of air service officers been delayed, hut, whereas officers of other arms had an opportunity for being initially commissioned in grades as high as field officers, the air service officers were limited to being commissioned in the grade of second lieutenant, with few exceptions. Furthermore, there was lack of promotion in the air service during the war, because it was a new corps. When the single list was compiled after the appointments of July 1, 1920, it was found that practically all of the officers, who were originally commissioned in the air service as flying officers, held tbe bottom files of the promotion list. That left vacancies in the grades of captain particularly, and these were filled, and are being filled, by officers transferred from other arms, who have had no war experience in air service activities and who are in many instances junior in age. The air service has a total of 900 officers, of whom over 700 are officers commissioned subsequent to April 6, 1920, and of this 700 about 500 are original flyers whose commissions were delayed, so that 200 of them are officers who were transferred from other arms or who came in as ground officers and are ranking the junior officers of the air service. The latest returns of the adjutant general's office show 608 first lieutenants in the air service, while in the infantry, which should have approximately three times as many as the air service, there are hut 1,008. The reason for this is that the majority of young officers in other arms, instead of heing first lieutenants, are captains.

The situation in the air service in respect to promotion has heen the subject of consideration hy the special

THE NEWS of THE MONTH

Navy Gets $6,537,000 to Build New Aircraft

Washington.—Inclusion of a Senate amendment of $6.537,000 in the naval appropriation bill for new construction of aircraft was agreed to June 21 by House and Senate conferees on the annual supply measure. It was the first meeting of the conference.

While the committees were discussing the appropriation measure Senator Pomerene (Dem., Ohio) announced in the Senate he had been informed that Admiral Wilson, Superintendent of the Naval Academy, had notified thirty civilian instructors there that their services were to be dispensed with.

The appropriation hill, as it passed the Senate, carried a provision for reducing the number of civilian instructors from the present 118 to 80 and Mr. Pomerene condemned the reported action of Admiral Wilson as presaging further attempt to get rid of the civilian instructors.

New York Flyers Forming Own Unit

New York is to have a flying unit all its own. There has been at Hempstead a temporary aviation squadron, but these men were part of the 102d Infantry, and when the unit is recruited will be transferred back to the 14th Infantry. Recruiting for the unit, which will be known as the 27th Air Service, has been started and a group of New York men who brought down many enemy aviators during the war have signed.

Among these are Major Kenneth Littauer, who was a member of the Lafayette Escadrille; Capt. G. De Forest Larner, who brought down eight enemy aeroplanes; Capt. Curtis Wheeler, who has six citations; Capt. George A. Vaughan, Jr., who has a record of thirteen enemy machines, the D. S. C. and British, French and Belgian medals; First Lieut. Howard Burdick, who brought down eight enemy planes, and nine other officers who did valiant service in Europe.

General Order No. 16, sent out from the State Adjutant General's office, authorizes the reorganization of the air service for the State Guard. It orders change of station to Miller Field, New Dorp, Staten Island, and allocates the seaplane hangar in the southeast corner of the 300 acres as the armory for the 27th.

Capt. G. L. Usher, U. S. A., is designated as the Regular Army air instructor for the National Guard. Capt. Usher already is in residence at Miller Field. The total strength will be 31 officers and 160 men, including a photograph staff of twenty and five intelligence men.

Tarkio, Mo., Flying Meet

The merchants and business men of Tarkio, Mo., are promoting an aero meet at Tarkio, July 27-8-9, inviting all flyers to compete in events, paying all expenses, such as gas, oil, hotel expenses and entertainment, and giving many cash prizes and cups and trophies. C. E. Tuttle is employed to manage the meet.

Tarkio is the home of Tarkio College, a town of about 3,000 population and very much alive.

The field selected for the meet is an 80-acre blue grass field one and a half miles south of town, with plenty of emergency fields adjoining.

The Larsen Trophy

The Contest Committee of the Aero Club of America on June 30th directed C. B. Wrightsman, of Tulsa, Oklahoma, to return to the Aero Club of Omaha, $3,000 in prize money, which it is alleged, was wrongfully awarded to him following the Larsen efficiency aeroplane contest, held in Omaha last November. This step, it was learned, is the first in the adjustment of a situation which has been the subject of discussion in American aeronautics for many months. John M. Larsen, donor of the trophy, whose entries in the race established undisputed performance, notwithstanding which the officials made the award to Wrightsman, has presented evidence supporting his claim that a fraud was perpetrated. Wrightsman is ordered to return the money within 10 days or be disqualified. Upon return of the prize money, further hearings will be held.

Spokane News

Captain Lowell Smith, one of the army air service's best known pilots and holder of several American air records, landed in Spokane at the municipal field at Parkwater on June 22 in a 400-horsepower De Haviland-Liberty motored plane. He is accompanied by Sergeant Whitefield.

Captain Smith is flying over the west, mapping all municipal and other landing fields for use of the government army flyers. He made the best time in the transcontinental air race two years ago, fighting a close contest with Captain Belvin Maynard, the "flying parson."

On his present trip out of headquarters at San Francisco, Captain Smith and his sergeant have photographed landing fields in California, Wyoming, Nevada, Utah, Boise, Montana and are now completing their map-making work in Washington.

They left next morning for the Coast, stopping en route to take field photos at Walla Walla, Yakima, Pasco, and other central Washington points.

He has covered 6000 miles since leaving California. Captain Smith and Sergeant Whitefield have been assigned to the photographic work by the air service.

The Bellanca Model C. F. Monoplane which made an excellent showing at the Monmouth Flying Meet

Digitized by Google

On an aerial tour from Buffalo, N. Y., to Siberia, C. O. Prest, aviator, landed in Spokane on June 21. He is making what he claims is the first transcontinental aerial travelogue moving picture ever taken and expects to cover over 8500 miles on his trip.

Prest carries a moving picture camera especially mounted so he can use it while operating the plane, and two ordinary cameras for still pictures. He took several hundred feet of film of scenes along the Spokane river in Spokane.

Aviator Prest has been flying since 1910, having flown first in the old Bleriot monoplane and the old-time Curtiss machines. A month ago he started on his cross-country trip. Before coming to Spokane he took aerial views in and around Glacier park.

La Porte Carnival

The Cleveland Air Transit Company is planning to hold an air carnival at La Porte, Indiana, on August 15 and 16.

Cincinnati News

Cincinnati will have no municipal airport for at least another year, is the announcement made today by C. W. Culkins, executive secretary of the Cincinnati Chamber of Commerce, due to the fact that the Government will not establish a reserve squadron station here and contribute the greater part of the finances. Mr. Culkins made the announcement after a statement to this effect had been received from Senator Frank B. Willis.

Regardless of the fact that there is no field at Cincinnati available for landing, the Cincinnati Aircraft Company is making rapid progress, and during the past week has made several sales, using a field near Harrison, Ohio, for its facilities. A small factory has been established at Second and Sycamore streets, where rebuilding and repair work is being carried on on a small scale. It is understood that this company will secure the services of Mr. D. W. Huntington, aeronautical engineer of Hempstead, N. Y., with a view to building a transportation ship. Negotiations are being carried on between the officers of the company and Mr. Huntington to this end, it was stated by Secretary M. H. Held, of the company.

Mr. H. F. Woolard has been appointed representative of the Cincinnati Aircraft Company for Indiana, with headquarters at Indianapolis.

New Aerological Survey Issued by Weather Bureau

Of special value to aviators is a section dealing with free-air winds, contained in a discussion of free-air conditions of pressure, temperature, humidity, density, and wind, as observed by means of kites, issued as Supplement No. 20 of the Monthly Weather Review by the Weather Bureau, United States Department of Agriculture.

The winds have been classified according to wind direction at the surface, and the average amount and frequency of veering and backing with altitude, increase in speed, percentage frequency of each direction, of north and west components, and of speeds above 10 and 20 meters per second have been determined and are presented in tabular and graphic form.

Many tables and figures are given in the supplement, and also a series of charts valuable to meteorological students. The marked difference between summer and winter conditions in the free air. as at the surface, though in less degree in the former is well brought out in these charts. It is a significant fact that the average direction and rate of movement of storms across the country are very nearly the same as the average wind direction and speed at heights of 3 to 5 kilometers. Measurements have been taken by kites up to 5 kilometers, or 3 miles.

This publication, which is available to interested persons upon application to the Weather Bureau, is Part I of an aerological survey, which will later include the diurnal variation at different heights, the results of observations with pilot balloons, and similar information.

Kansas City Activities

Plans for an airdrome which will make Kansas City a leader in aeronautical activities were announced on June 18, by the Flying Club. A 53 acre field, which will be leased to the government and operated under supervision of air service officers is being purchased by Major Howard F. Wehrle, Rogers Crittenden, Frederick H. Harvey, Robert E. Lester and Simpson Yeomans.

The site which has been approved by Major Ira A. Rader, of Fort Crook, Neb., corps area air officer, and Capt. St. Clair Street, a member of the National Airways board, is on the Davenport road a few hundred feet south of Blue Ridge boulevard on the way to Rayton.

Plans for the development of the field are tentative, include:

Eight hangars, arranged about the rectangular field, two garages, and a machine ship, motor car parking space, a grand stand with a capacity planned at five thousand, space for a clubhouse for the flying club, space for an aviation school, where civilian fliers may be trained. This would be a privately owned concession.

Quarters for the civilian flying school, barracks and similar enterprises, and a field marker in the center of the field with "K. C." lettered in colors on a white background.

The field will be used by the government and civilian aircraft. It will be used by the government for army operations and training purposes. Principally for the training of reserve officers. Also the air mail will be accomodated at this field in addition to the establishment of the national guard aviation squadrons at this place.

Boston is the only city which has taken advantage of the government plan of leasing privately purchased ground for an airdrome, so far. Other cities which have similar plans are San Francisco, Chicago, New York, Los Angeles and Minneapolis, it is reported.

Major Wehrle who was active in securing the field, is particularly well equipped to direct successfully a project of this kind.

Pilot Chas. Pedley and Mrs. Pedley, who are doing good work in the Southwest and West

Digitized by Google

He superintended the laying out of Hazelhurst field, Mineola, New York, the first government school in the East and the second in the United States. He was one of the early aviators who took training with the Curtiss company in 1916. When the war broke out, he was a Captain in the air service, and was immediately assigned to the task of preparing plans suitable for aviation fields. His plans were copied by various fields about the country.

According to the plans of the five men, an Air Terminal association will be establisbed and incorporated with $40,000. Stock will be sold, and facilities on the field will be provided for by the corporation. Five hundred square feet of ground on the terminal field will be let to the flying cluh for the building of a clubhouse. In addition the club will carry on their activities on this field free of rent or charge. The old American Legion field at Sixty-seventh street and Belinder road will be abandoned as soon as the lease expires on November 1, 1922. A new hangar there which is nearing completion will be moved to the new field, according to plans of the flying club. Also all other facilities will be transferred to the new field or other points. There are now twelve ships on the present field, all actively engaged in flying. Much of the flying is done in passenger carrying and training of pilots.

Following the announcement of the plans for the terminal, Mayor Frank Cromwell voiced approval of the new enterprise and urged the early developments, that Kansas City might get ahead as rapidly as possible.

"It is not only a matter for those who are directly interested in flying to think about," the Mayor said, "but it is a civic matter and will be a distinct asset to Kansas City."

At present the final details and purchase of the field depends on Washington. As soon as the lease is signed by the government, work on the hangars and the field will commence. It is said that the new airdrome will be completed by the first of the coming year.

The Air Service plans to send ten planes and a detachment of six men, one officer and five enlisted men, who will supervise activities.

At a meeting of the flying club in the hotel Baltimore, June 22, evening, after three hours' debate, the club decided to indorse the project and accept the plans of the terminal association. At first much opposition to the plan was voiced by Francis Poindexter and a committee of four men. They argued that should the club accept the proposal of the association, Kansas City's aerial activities would fall entirely into the hands of five men, that the club would lose its prestige and would no longer be the city's leading faction in the promotion of flying.

Several squadrons of reserve officers of the air service are established in the vicinity of Kansas City and with these organizations eager for active participation in flying along with civilian flying much activity is apparent for Kansas City. Two manufacturing concerns are considering branch factories here in addition to three air lines which are proposed from Kansas City to Chicago, from Kansas City to Oklahoma City and from Kansas City to St. Louis. The main sales office of the Huff Deland aero corporation is established here, and plans are on foot to move the factory from Ogdensburg, N. Y. to Kansas City. Also the Longren Aircraft of Topeka, and the Laird Swallow company of Wichita are now preparing plans for active work in Kansas City. The Laird Swallow company is establishing a regularly operated air line between Kansas City and Wichita which will be in operation as soon as two large planes for the purpose are completed.

Petitions for the establishment of an air mail terminal are also under advisement. The association hopes to bring this service through Kansas City before the year expires. Two new flying schools are in preparation, and in addition to passenger work, much of Kansas City's advertising in the nearbly states is carried on by aeroplane. The Victor Oil company here have two planes which are used to carry their salesmen about the country.

Spokane News

Co-operation of local aircraft companies, centralization of activities and a comparatively small amount of money spent on the Parkwater municipal field will give Spokane aviation facilities second to none, Captain Lowell H. Smith, famous army flyer, said while in Spokane recently.

In his big De Haviland plane, driven by a 400-horsepower motor, he left Spokane, circled the field, the city and Fort George Wright, while taking aerial photographs, and then soared away to the west, headed for Yakima.

In the interests of the Army air service Captain Smith and his aide are making a 6,000-mile trip over the West, mapping the principal landing fields. He will take back pictures of 75 fields when he reaches headquarters at the Presidio, near San Francisco.

"Parkwater Field is the best I have seen since leaving Cheyenne, Wyo., which is on the Government aerial mail route," Captain Smith said. "It is large enough for a four-way field and one of the best in the country. The city or somebody should devise some means of clearing parts of the field of rocks which now dot the surface and which might cause someone to damage a ship.

The Dirigible Mooring Tower at Lakehurst, New Jersey

"Your aerial activity at Spokane should be centralized. All flyers here should co-operate to make the business a success and should all put their ships at the one field. With all flying from one field, there would always be someone ready to go into the air and far better results would be obtained."

Captain Smith says Spokane has one of the few fields in the West suitable for teaching beginners flying work. Its size, he said, affords beginners far greater safety.

The Commercial Club at Walla Walla, Wash., obtained an indefinite lease on a tract of land one mile east of the city for use as an aviation field. The land is owned by Eugene Tausick and the Baker Langdon Company and can be leveled at little cost. The owners agreed to let the club use the land without cost. Several automobile dealers have agreed to furnish tractors to help level the ground. This is the first step in a movement to put Walla Walla on the aerial route. The field will be available to any aviator who happens to be traveling through and will be suitahly marked so that it can be plainly seen from the air.

Air Mail Performance

At 12 o'clock Sunday night, July 16, the Air Mail Service of the Post Office Department completed a year's daily service without a single fatal accident. During this time the planes flying on the New York to San Francisco route covered 1,750,000 miles. More than 49,000,000 letters, totaling 1,224,500 pounds, were transported.

The record of the Air Mail Service for the past year proves more conclusively than any other test ever made the reliability and the efficiency of the aeroplane in commercial service. Through every kind of weather, summer, fall, winter and spring, and over mountains, deserts and forests, the Post Office Department air mail planes flew. The percentage of trips actually completed was 92.5 per cent, as compared with 83 per cent for the last fiscal year. The percentage of scheduled miles actually flown was even higher, totaling 94 per cent.

While routes totaling 820 miles were discontinued during the last fiscal year and only the transcontinental route of 2,680 miles maintained, the Air Mail Service nevertheless carried the same amount of mail as it did last year, or 23 per cent more in each aeroplane load.

Officials of the Air Mail Service attribute the record of no fatal accidents in a year to the fact that all their pilots now are experienced and tried and they know the route. That the pilots of the Air Mail planes of the Post Office Department are top-notch among the flyers of the United States was established at a recent Midwestern flying meet at Monmouth, Ill. Here the flyers of the Air Mail Service took five events of the eight and six cups of the nine given as prizes. The mechanics, too, are more experienced. Last year was a pioneer year. Then the pilots were learning the routes they were flying and the field and hangar equipment was inadequate. During the fiscal year ending June 30, 1921, seventeen people died in accidents in the Air Mail Service. Many of the fatalities occurred with the metal monoplanes which were abandoned. During the last fiscal year one pilot was killed. His death occurred on July 16, 1921, but no man has met death in the Government Air Mail Service since then. In the last year no flyer has been in the hospital more than five days.

The Air Mail Service is now maintaining sixteen stations on the ocean-to-ocean route. Fifty-six planes are ready to fly. In addition, some are being overhauled and some are in storage waiting to be assembled. The Air Mail Service is employing forty of the most expert pilots in the United States. The total number of men employed to fly the planes and to keep them in repair is 372. Every day twenty-one pilots and planes are in the air, flying approximately 6,000 miles. The speed possible by the use of the Air Mail is shown by the fact that mail sent from New York has been delivered in San Francisco three days later.

The Post Office Department expects to establish night aerial mail service on the transcontinental route within this fiscal year. At present the planes are used chiefly to advance mail delivered too late to catch trains on which earlier mail left, but night flying planes will carry mail from New York to Chicago or from Chicago to Cheyenne.

(Concluded from page 401)

a definite plan. For months there had been under consideration a flying meet and congress, but definite action was not practicable until the last fortnight, when a representative of the Chicago Aeronautical Bureau called on us. The plan is to hold a flying meet and convention, August 4 to 13, to which no admission will be charged. The purpose is to develop Chicago's position in air transportation. The president of the Chamber and others, including Messrs. Curtiss and Redden, have accepted invitations to speak. The meet, as presented to us, has our hearty approval and it is recommended that the Chamber sanction it and otherwise assist it in every way possible.

Aeronautical Institute: There has been under consideration the desirability of an Aeronautical Institute. It now appears that at the time of the Pulitzer Races in Detroit the program of the Detroit Aviation Society includes the organization of an Air Congress in connection with the effort that is being made to perfect the National Aeronautic Association. In the replies that we have received to our questionnaire on this subject there is considerable divergence of opinion on this subject. This, in a measure, is due to a misunderstanding of aims, scope and purposes of such a plan. Many of our members assumed that an Air Institute would be limited to consideration of engineering problems and consequently recommended that the work be left entirely to the S. A. E. As a matter of fact, a program for an Aeronautical Institute would not only include papers on engineering subjects, but consideration of questions of aerial law, national and international policies, insurance, military and naval use of aircraft, organization of aerial transportation companies, both as to personnel and finance, etc., etc.

Co-operation with Local Chambers of Commerce

As we are increasing our contact with local Chambers of Commerce we receive increasing demands from these organizations for co-operation. They are gradually forming the habit of not only referring to us the peculiar questions of their locality regarding landing fields and the establishment of air lines, but the inquiries that they receive from individuals on aeronautical questions.

Sales Information

We have an increasing number of requests for information regarding sources of supply for aeronautical material, which is regarded as a very wholesome sign, not only as indicating the manner in which our organization is being used, but the increasing interest on the part of the public in aeronautical development.

President Harding's Letter

Following is the letter, mentioned above, which the Aeronautical Chamber of Commerce received from President Harding:

"The White House,
"Washington.

"Gentlemen:—

"I find pleasure in adding a word expressive of my interest in aerial transport, and in the presentation of the subject which is being made by the Aeronautical Chamber of Commerce. The history of civilization is largely the history of communication. Each stage of progress seems to demand and develop improved means of transport. The steamship, the railroad and the motor car have been devised and utilized. Now we enter a new phase. It is a real distinction to America to be known as the birthplace of the aeroplane; it should be our concern that this art shall not languish, but that in its practical application we shall lead the world. An amazing development will take place in the near future in the utilization of the air as a medium of transport and communication. As a government, we are aiming to provide this art with necessary guaranties of law, and with such facilities as may be possible through the encouragement of airways and terminals. But for air transport quickly to achieve the important place it is destined to occupy it must have public interest and support. I hope your efforts in this behalf may be productive of most gratifying results.

"Very truly yours,
"WARREN G. HARDING.

"Aeronautical Chamber of Commerce of America, Inc., 501 Fifth Avenue, New York City."

New York-Atlantic City Service

Passenger accommodations to fill a six-place flying boat daily from Atlantic City to New York have been booked for one month in advance, the Aeronautical Chamber of Commerce announced in connection with the regular daily service each way by Aeromarine Airways. Their flying cruisers will leave the municipal flying station at Eighty-second street, North River, every afternoon at four o'clock. The flying boats will leeave the Curtiss Airport at Atlantic City at ten o'clock in the morning for New York. The trip between the two cities is made entirely over the water. It will require only 75 minutes, as against three and a half hours by train.

B-G Expansion

Owing to the fact that the demand for B-G spark plugs has increased so tremendously the company has had to take larger office and factory space at 136 West Fifty-second street, New York.

Navy Department Test of Wright Engine

The Navy Department has had a quiet way of doing a considerable amount of development work on aircraft engines during the past two years. An interesting evidence of this is the recent completion of test of 250 hours on a Wright E-2 engine. This engine was run for two periods of 125 hours each. One hundred and twenty-five hour runs were continuous, twenty-four hours a day, the only stops being three in each period due to gasoline shut off, trouble with oil radiator leakage, spark plug renewal and the necessity for club renewal, as part of the test was conducted in a rainy period.

This engine was run at the rated horsepower of 180, and a rated speed of 1800 r.p.m. on straight aviation gasoline. While the results of the test are not for publication as yet, it is understood that the Navy Department is well pleased with the tremendous durability shown by the engine and it is also understood that the Wright Company intends to incorporate in future production engines several modifications of the standard E-2 which were tried out during this test. Representatives of the Wright Corporation who observed the test are enthusiastic about the way the men of the Bureau of Aeronautics on duty at the Naval Air Station at Anacostia, D. C., handled the running of this very arduous bit of research work. One of the most interesting points in connection with this endurance test is that the connecting rod bearings, which were the weakest point in the original type "A," 125 H. P. Hispano engines, from which the present engine was developed, ran for the full 250 hours and showed no measurable wear in that period; also that the valves which were regarded as being very delicate in the early engines were in such a condition at the end of the test that they would have undoubtedly run another full period of 125 hours.

Flying School Data Wanted

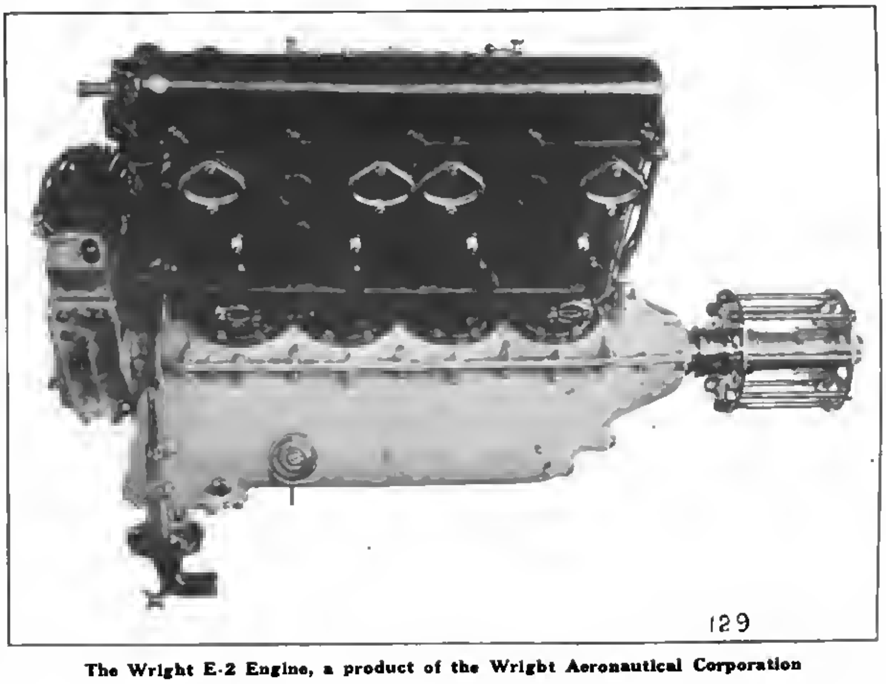
The Aeronautical Chamber of Commerce are preparing data on flying school activities during the past year, and all schools are requested to send the approximate number of pupils turned out during the past 12 months, with photographs of activities where practicable.

Photographic Opportunity

The Aeronautical Chamber of Commerce has received a communication from Mr. Theodore G. Holcombe, Secretary of the Committee on Post Office and Postal Facilities, of the Boston Chamber of Commerce, 177 Milk Street, Boston, Massachusetts, requesting information relative to the cost, etc. of an aerial survey of Boston. He desires, for his files, the names, etc. of reliable firms engaged in aerial photography, that they may be available in case an aerial survey is decided upon.

Standard Atmosphere

Report No. 147 of the National Advisory Committee for Aeronautics, by Willis Ray Gregg, discusses the need of a standard set of values of pressure, temperature and density at various altitudes and points out the desirability of adopting such values as are most in accord with actual average conditions, in order that corrections in individual cases may be as small as possible. To meet this need, so far as the United States is concerned, all free-air observations obtained by means of kites and balloons at several stations in this country near latitude 40° N. have been used, and average values of pressure, temperature and density, based upon those observations, have been determined for summer, winter and the year and for all altitudes up to 20,000 meters (65,000 feet). These values are presented in tables and graphs in both metric and English units; and in the tables of densities there are also included values of density for other parts of the world—more particularly for Europe. A comparison with these values shows that, except in the lowest levels, the agreement is very satisfactory. A further comparison with



The Wright E-2 Engine, a product of the Wright Aeronautical Corporation

Digitized by Google

values of density determined from Toussaint's law of temperature decrease, t = 15 — .0065z, in which t is the temperature in ° C and z the altitude in meters, indicates very good agreement with those values up to 10 kilometers. It is therefore recommended that the United States adopt Toussaint's values of density up to 10 kilometers and the values presented in the tables for all higher altitudes.

A copy of Report No. 147 may be obtained upon request from the National Advisory Committee for Aeronautics, Washington, D. C.

Triangle Airways

The Triangle Airways of Chicago operated their two six-passenger flying boats from Chicago to Michigan City on July 4, to transport fans to the Leonard-Rocky Kansas bout. Short flights are made regularly by the company from the old Columbia Yacht Club.

The Slotted Wing

We are in receipt of the following letter from C. A. Wragg, aeronautical engineer, Washington:

In the article on the "Theory of the Slotted Wing" by A. Betz, Gottingen, printed in your issue of June 26th, reference is made to the type of wing system (Fig. 5) in which a wing section is set close behind and below another to make a compound aerofoil unit for normal flight. It is stated that the flow about the forward wing is improved by the proximity of the rear one, but that the effect of the forward wing on the flow about the rear one is such as to detract from the advantage gained.

The writer pointed out this improvement on a forward section in such a wing system years ago, and also stated that not only could the detractive effect on the rear wing be minimized sufficiently to make the arrangement worth while as a fixed non-adjustahle system, but that the airflow about a rear section set close behind and helow can be affected in such a way as to augment the efficiency of each section and result in improved efficiency of the compound. He claims to be the first to point this out and has for many years advocated and endeavored to instigate a thorough investigation of this Compound Aerofoil.

Qualitative data obtained hy the writer indicate that not only can the L/D be improved by emhodying the requirements which he specified, hut that this can be in a measure affected by reduction of drag at the low angles and values of lift used for maximum speed.

The system can therefore he ideally adapted for high speed, and hy making certain simple mechanical adjustments it can be changed during flight to considerably increase the lift coefficient by reducing or closing the gap (the reverse operation of the Lachmann and Handley Page idea) for the purpose of landing and rising.

Aeromarine Airways Opens Great Lakes Division

The Aeromarine Airways, Inc., officially opened a daily flying boat service between Detroit and Cleveland with the arrival of two eleven-passenger, closed-cabin flying boats, the *Santa Maria* and the *Wolverine*, in Cleveland after a 90-minute flight from Detroit on July 14.

On board the *Wolverine*, which was piloted by E. D. Musick, were C. F. Redden, president of the Aeromarine Airways, Inc.; W. E. Metzger, president of the Detroit Athletic Club; Commodore A. A. Schontz, president of the D. & C. Steamship Company; P. J. Reid, managing editor of the Detroit *Free Press;* H. V. Wilcox, of the Detroit *News*, and Roland Rohlfs, Detroit manager of the Aeromarine Airways, Inc.

On board of the *Santa Maria*, which was piloted by D. G. Richardson, were I. M. Upperque, president of the New York Cadillac Motor Car Company, and owner and president of the Aeromarine Plane & Motor Company, the parent corporation; C. F. Ketterling, vice-president of the General Motors Company; Dr. J. W. Inchec, Commissioner of Police of Detroit; Carl Fritchie, of Detroit; Frank Lewis, of New York; T. Norris, motion picture photographer; C. S. Mott, general manager of the General Motors Company, and a representative of the Detroit *Journal*.

The boats arrived at Cleveland at 12:20 p. m. The distinguished passengers were greeted by a committee from the Cleveland Chamber of Commerce. Glenn L. Martin, of the Glenn L. Martin Aircraft Corporation, headed the welcoming delegation. H. A. Bruno, sales and advertising manager of the Aeromarine Airways Company, and Walter Hempel, field representative of the company, were also at the dock when the boats arrived.

The visitors and welcoming committee were driven in Cadillac automobiles from the dock to the Cleveland Chamber of Commerce. The procession was escorted by a troup of mounted police. At the Chamber of Commerce they were met by Mayor Fred Kohler, and Newton D. Baker, president of the Chamber of Commerce, gave an address of welcome and complimented Mr. Upperque and Mr. Redden on the initiative shown by the Aeromarine company in developing commercial aviation in America.

The party returned to the flying boats at 3 o'clock p. m. and at 3:22 p. m. the boats left the water on their return flight to Detroit, arriving there at 4:41 p. m.

The Cleveland station of the Aeromarine Airways, Inc., is at the D. & C. dock at the foot of East 9th street. Tickets and reservations may be made at this station and also at the uptown office of the D. & C. company, 2010 East 9th street.

In Detroit the operating base is in the Memorial Park and the river. The downtown passenger station is at the foot of First street. Tickets may also be had at the D. & C. offices. The operating equipment for this service is up-to-date in every way. Fast motor boats and base floats were shipped from the Aeromarine factories at Keyport, N. J., and are stationed at the different bases. Through the cooperation of Commodore Schontz, Aeromarine passengers have the use of the D. & C. waiting rooms at both cities. The boat schedules are as follows:

Leaves at 9 a. m. from Cleveland and Detroit. Returns at 5 p. m. from each city. The fleet consists of the *Santa Maria*, the *Wolverine*, and a six-seat open boat, the *Niagara*. Another eleven-passenger flying cruiser has been ordered from the factory and will join the fleet within a few days. This boat was named the *Buckeye*.

Air Mail Radio Service

Plans are being considered by the Post Office Department for changing at least a few of the fifteen radio stations operated in connection with the Air Mail Service to provide both radio telegraph and radio telephone service. The stations are at Washington, D. C.; Hazelhurst, L. I.; Bellefont, Pa.; Cleveland, O.; Bryan, O.; Chicago; Iowa City, Ia.; Omaha, Neb.; North Clark, Neb.; Cheyenne, Wyo.; Rock Springs, Wyo.; Salt Lake City, Nev.; Reno, Nev., and San Francisco.

The Washington station has had both radio telegraph and radio telephone service for nine months. Besides maintaining an hour-to-hour record of the progress of air mail, the Post Office Department radio stations now send out other information. Complete weather reports now go out daily. Also reports of grain, dairy and livestock prices travel the ether waves to the farms and farming communities.

It is still uncertain just when the stations will be changed to radio telephone apparatus. Because of the first call on the radio by the Air Mail, the equipping will probably be gradual. Further announcements concerning the new service are expected within a short time.

ARMY and NAVY AERONAUTICS

Navy Prepares for Detroit Races

The Navy is making extensive preparations for the forthcoming aerial contests to be held in Detroit in October and it is hoped and confidently expected that the Pulitzer Trophy and the Curtiss Marine Flying Trophy will fall a prize to Navy contestants.

In the Pulitzer Race, the Navy will make five entries, among which will be the Curtiss Navy Racer CR-1, winner of the event in 1921. This plane holds the world's record for a closed circuit. The CR-2, another entry, is a modification and improvement over the CR-1, and will undoubtedly be heard from. Two Booth Racers, BR-1, supplied by the Aerial Engineering Corporation, have a designed speed of 216 miles per hour. One MB-7 (Thomas-Morse Monoplane) of tried and proven ability and having exceptional qualities of manoeuverability will be entered, and stands an excellent chance of winning the race.

In the Curtiss Marine Trophy Race, the Navy will have ten and possibly eleven contestants, which include two TRs, two TSs, and two Curtiss Triplanes, 18T type. Other entries in the Curtiss Race will be an HA Fighter, a Gallaudet D-4, an H-16, and a VE-9.

Intensive training of pilots is projected for the summer in preparation for the contests. They will be sent to Detroit in September and there continue training and familiarize themselves with the course.

The Detroit Races were originally scheduled for September, but recent advices from The Detroit Aviation Society postponed the dates of the Curtiss Race to October 7th and of the Pulitzer Race to October 12th.

The Baby Bomber

The air flivver has arrived. It is driven by a 17 horsepower motor taken from a popularly known motorcycle, which its huilder used to ride.

This little plane was constructed at McCook Field hy O. H. Snyder, one of the aeroplane experts. It is 16 feet in length and has a wing spread of 21 feet. It weighs less than 400 pounds and is the smallest thing that flies at McCook Field, where it is affectionately called the "Baby Bomher."

Lieutenant John A. MacReady, who holds the world's record for altitude, 42,800 feet, recently put the Baby Bomber through her paces in a two-hour flight. She did everything that a regulation plane can do. On a straightaway flight she made 62 miles an hour, was then throttled down to 21 miles an hour in landing and came to a dead stop in 40 feet. In taking the air she requires a runway of from 150 to 200 feet.

MacReady declares the little flier rides easy, is well proportioned and evenly balanced.

Snyder superintended the construction of the baby and built nearly all of it himself. Consumption of oil and gas is no greater than that required to send a motorcycle down the pike at 45 miles an hour.

Snyder believes that his little machines can be developed commercially and fill a need which is manifesting itself in aviation.

A Chain of Air Routes Across the United States

The latest project of the Airways Section, Office Chief of Air Service, is the formulation of a plan for the thorough investigation of practically 90 per cent of the proposed Airway System of the United States. Letters of instructions have already heen sent out to the various Army Air Service flying fields, designating certain routes over which pilots from those fields should fly. Upon the completion of the initial investigation of the routes tentatively selected, and after a decision is reached as to the most advisable routes to fly over, the Army Air Service contemplates making arrangements for the inauguration of a regular bi-weekly aeroplane patrol over these routes, to enable pilots of the various fields to ascertain from time to time the condition of landing field facilities in the district allotted to them.

Pilots will be required to promptly report any field previously selected which has since been plowed up or otherwise rendered unsuitable for landing.

The object of establishing a system of air routes across the continent is to enable the Army Air Service to plan cross-country flights of a special nature, such as maneuvers, etc.

The establishment of this transcontinental airway system should prove of material aid to commercial flying and stimulate long-distance flights. Flights across the United States will not be of such a rare occurrence as at present, and it is possible, in view of the great saving of time, such flights will become popular, since they will curtail a journey of at least five days by train to two days at the most.

Transfer of Photographic School

The transfer of the Photographic School from Langley Field to Chanute Field, Rantoul, Illinois, marks the removal of what may be considered as one of the landmarks of Langley Field. The original school was established here in the Summer of 1917, soon after the organization of the Photographic Division of the Signal Corps. British advisory officers in the persons of Major Campbell and

The Baby Bomber designed and constructed by O. H. Snyder at McCook Field

Digitized by Google

Sgt. Major Haslett were among the first to arrive to teach the new use of photography from aircraft. These officers were also pioneers aerial photographers of the British Army.

At this time, Langley Field was just beginning to take form. The first Photographic School building was built by the students, many of them newly commissioned reserve officers. The personnel was at first quartered in what was known as the "old red barn," only the foundations of which may now be seen. The first class was graduated in the Fall of 1917, and some of the graduates were sent immediately overseas, others to flying fields and still others established schools of aerial photography at Post Field, Cornell University and Kodak Park, Rochester, N. Y. The latter was probably the largest school of photography ever operated, having had, at one time, as many as 800 students under instruction. The Cornell school a few months after its establishment, became the training center for photographic officers.

With the organization of other schools, the parent school became the school for aerial observers and continued as such until the Armistice. After the closing of the schools at Rochester and Cornell, the Air Service Photographic School, as it is now constituted, was re-established at Langley Field in the Summer of 1919.

The photographic laboratories and facilities of the Photographic School are probably unsurpassed by any similar school. Since its establishment three years ago, upward of fifty officers and one hundred and fifty enlisted men have been graduated.

Mexican Officers Visit Kelly Field

General Covarrubias, of the Military College of San Jacinto, Mexico, with his staff, visited Kelly Field on May 16th and was highly pleased with the aerial demonstration given at the field and much impressed with the possibilities of bombardment and attack aircraft in use against rebels and bandits in his country. The 2nd Photo Section took a number of pictures of the General's party and they were developed, printed and dried, labelled and presented to the party before they left the field. Four formations of five planes each passed before the reviewing stand in honor of the visitors.

Admiral Fullam Praises Bombardment Pilots

The morale of the Bombardment Group at Kelly Field went up another peg following Rear Admiral Fullam's address in San Antonio recently on the "Possibilities of Aviation," in which he praised the unparalleled feats of the bombardment personnel in the battleship sinking business last summer on the Atlantic coast and foretold some of the amazing possibilities of aerial bombardment. Of course, the members of the Group know all these things, but they like to hear others say them just the same.

Advanced Students at Kelly Field to Graduate

The present class of student officers and cadets has about finished their advanced bombardment training. There has been only one major crash during the present class. Cadet Halpin, on May 16th, attempted to make a forced landing in a small muddy field and wrecked the aeroplane. He escaped without serious injury.

Spraying New England Forest

Following previous experience in connection with the spraying of trees by aeroplane, plans have been formulated for spraying a section of the New England forest by this method. Captain R. A. Kinloch, Air Service, on duty with the 1st Squadron at Mitchell Field, L. I., New York, was detailed on this duty and departed for Boston, Mass. He investigated landing field facilities in the vicinity of the forest to be sprayed, and has been in consultation with the representative of the Department of Agriculture who was assigned to conduct the experiment.

Setting Up of Martin Bombers

The L. W. F. Engineering Corporation recently completed setting up and testing the first of the thirty-five Martin Bombers to apply on their contract for the Government. The first plane was flown by the test Pilot, Lieutenant Wade, of McCook Field to the Aero Marine Plant at Keyport, New Jersey, to be used as a model Work is now in progress by the Curtiss Corporation in setting up at Mitchel Field the first of the Martin Bombers which that corporation is building for the Army. This plane is now practically ready for test. It is understood that the Curtis Corporation will turn out one Bomber per week, all of these to be set up at Mitchel Field.

High Parachute Jump at Kelly Field

Master Sergeant Chester W. Kolinski, of the 90th Squadron, stationed at Kelly Field, San Antonio, Texas, made a successful parachute jump on May 24th from an altitude of 10,600 feet, so far the highest jump made by any member of the parachute school during the present course. The training pack chutes were used, and the ship was piloted by Lieutenant J. H. Doolittle. Both chutes functioned perfectly.

A Memorial at Love Field

At the entrance to Love Field, Dallas, Texas, there now stands a small granite monument, which was dedicated on May 30th last in memory of the twelve officers and cadets of the Army Air Service who made their last flight at that field. As Love Field is to be abandoned as a flying field and may soon lose its identity, this landmark was erected in their honor. The memorial bears the individual bronze name plates which formerly hung in the Officers' Club at that field.

The dedicatory services were very impressive, and hundreds of people were present to pay their silent respect to the memory of the departed flyers.

General William R. Smith, commander of the 36th Division and veteran of the World War, paid a high tribute to the momory of the men who gaves their lives during America's hour of stress. He declared that the progress of the aeroplane in the last war has shown conclusively that this method of warfare will continue to grow in importance, and that in event of future wars a still greater part will be played by the plucky and fearless men of the air. "They are honored dead," he said. "What they did in their struggles to master the air will be felt immeasurably as time flies on. Those martyrs who staked their lives in preparing for their needed service overseas did not die in vain. We owe them all honor and credit." As he stepped from the raised platform, he swept his cap from his head, which was the signal for the planes sent from Kelly Field, Ellington Field, Post Field and Love Field to take the air and circle the field. The planes rose gracefully and passing over the memorial shaft in rapid succession showered wild flowers upon the granite slab.

Other speakers were Herman Whisnant, who was an officer of the First Division and lost his leg in the Soissons campaign; Charles L. DeBow, chairman of the arrangements; Major Jed C. Adams, and Mrs. S. M. Fields, president of the Southern Memorial Society, who placed beautiful wreaths on the stone, with short impressive and touching remarks. Near the front of the shaft the emblem of the American Air Service was placed by the women of Love Field.

The officers and cadets whose name plates are on the monument are as follows: 1st Lieut. Rex Everett Field, 2nd Lieutenants Charles James Hyde, Parker Pruce, John Maxwell Widenham, Arthur Anthony Sego, Jr., Ralph Phelps Collier, Robinson E. Bidwell and Cadets Victor Leon Dennis, John William Albert Insinger, Ralph Eldon Stall and James Forester Dick.

This memorial was the idea of Lieutenant Marion G. Putnam and

Digitized by Google

was his personal contribution to the memory of these men, many of them having been his friends.

General Patrick Visits Chanute Field

General Mason M. Patrick, Chief of Air Service, and his party, arrived at Chanute Field by aeroplane from Milwaukee on Wednesday, May 31st. The officers comprising the party were Major H. A. Dargue, Major P. Van Nostrand, Major Wm. C. McChord, Air Officer, 6th Corps Area; Capt. W. C. Ocker and Lieut. H. K. Ramey. General Patrick made a thorough inspection of the field and left on Friday, June 2nd. Major Van Nostrand remained at the field and accompanied Lieut. Frank M. Paul on a cross country trip to Iowa City, Iowa, and thence to Scott Field, Belleville, Ill. Lieut. R. R. Fox also made this trip, the purpose of which was to map an air route from Scott Field to Chanute Field and other points.

Aerial Ambulance

Under orders from the Department of War all flying fields in the United States are to be equipped with the new type of aero ambulance recently developed by the engineering division at Wilbur Wright Field, the largest aerial supply depot in the Army Air Service.

Ambulances are in various stages of construction at the present time and will be delivered to the fields as rapidly as they are finished.

The new type is known as the Curtiss J N 68. It is driven hy a 180 horse power Hispano motor.

The litter carrier or stretcher compartment is located in the fuselage near the center. It is entered through a door in the side and extending across the top. It is connected with the physician's cockpit by means of portholes. The pilot's cockpit is right out in front.

The first model built has been successfully tested and given the official O. K. by the department.

Promoting the Establishment of Landing Fields

The trip recently made by Captain St. Clair Streett, Air Service, on duty in the Airways Section, Office Chief of Air Service, for the purpose of making a general survey of landing field facilities in the Eastern and Middle West sections of the United States, was productive of excellent results and, it is helieved, will ultimately result in the establishment of a network of landing fields in these sections of the country which will go a long way in not only extending the field of commercial aviation but also in increasing the element of safety in flying.

In the various localities visited by Captain Streett the various commercial aeronautical concerns, as well as the municipal authorities, aero clubs, chambers of commerce, etc., were made acquainted with the efforts being made hy the Army Air Service to encourage the growth of commercial aviation. Captain Streett states that at those places visited where commercial aviation concerns had been actively operating there prevailed a marked enthusiasm for aviation and a willingness to co-operate in any manner possible. It is his contention that it is the duty of every Army pilot to educate the public in the safe and sane usage of the aeroplane; with the fact that by its use one is enahled to cover long distances in a short space of time; that with the existence of adequate landing fields regular schedules of flight can be maintained without interruption, since with aviation equipment developed to its present degree of efficiency it is very seldom nowadays that it is found necessary to postpone flying on account of unfavorahle weather conditions.

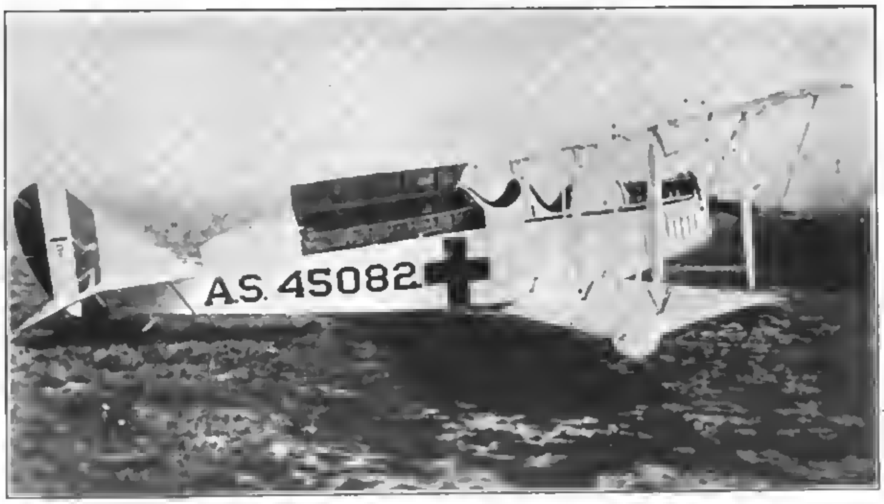
Aside from the primary purpose of the trip, that of boosting commercial aviation and securing all available information on landing field facilities, much useful data was obtained which will aid in the preparation of standard maps.

The itinerary of the trip was as follows: Moundsville, W. Va.; Columbus, Ohio; Dayton, Ohio; Indianapolis, Ind.; Louisville, Ky.; Camp Knox, Ky.; Kokomo, Ind.; Wabash, Ind.; Lafayette, Ind.; Rantoul, Ill.; Belleville, Ill.; St. Louis, Mo.; Fulton, Mo.; Kansas City, Mo.; Fort Leavenworth, Kan.; Lincoln, Neb.; Omaha, Neb.; Des Moines, Ia.; Cedar Rapids, Ia.; Iowa City, Ia.; Davenport, Ia.; Monmouth, Ill.; Chicago, Ill.; Milwaukee, Wis.; thence back to Dayton, Ohio; Toledo, Ohio; Camp Perry, Ohio; Cleveland, Ohio; Buffalo, N. Y.; Rochester, N. Y.; Syracuse, N. Y.; Utica, N. Y.; Schenectady, N. Y.; Albany, N Y.; Boston, Mass.; Hartford, Conn.; New York City; Baltimore, Md.; Washington, D. C.

Despite the fact that for five days during the trip between Dayton and Rochester rainy weather prevailed practically the whole time the plane was in the air, the whole trip was accomplished without incident. The plane used was a DH4B, which covered approximately 4,000 miles, the entire trip consuming five weeks.

Dr. S. M. Burka, of McCook Field, accompanied Captain Streett on the trip from Dayton to Omaha and return, while Lieutenant George W. Goddard was the passenger on the remainder of the journey back to Washington. Photographs were taken of all possible landing places whenever the weather permitted, and sketches were made of all fields visited.

Data was obtained from commercial aviation operating companies on their past operations and on their plans for the future. A number of cities visited either have adequate landing facilities or contemplate the immediate establishment of same, viz.: Louisville, Columhus, Kokomo, Wabash, St. Louis, Fulton, Kansas City, Lincoln, Omaha, Des Moines, Davenport, Monmouth, Chicago, Milwaukee, Buffalo, Rochester, Utica, Schenectady, Albany, Boston, Hartford and Baltimore. At the present time facilities are available at all of these cities where landings can be effected, and at every one of these cities the Chamber of Commerce and civic officials, as well as commercial aeronautical firms, invite Army and civilian pilots to use their facilities. Detailed information with regard to the landing facilities at the above-mentioned localities can be obtained from the Airways Section, Office Chief of Air Service, Washington, D. C.



U. S. Army Type Aerial Ambulance

A British Cross-Channel Seaplane Serivce

An Air Ministry communiqué, issued on June 14th, makes a definite statement as to the cross-Channel seaplane undertaking which has for some time past been the subject of vague rumor. The scheme, which is to be operated by a company now in process of formation, probably with the title of "The British Marine Air Navigation Company," has been approved by the Air Ministry, and will be operated under the general terms of the subsidy scheme which was published in June, 1921.

Services are to be run by seaplane between Cherbourg and Southampton, and Le Havre and Southampton, the main object of the scheme being (a) to shorten the cross-Atlantic journey to London by picking up passengers at Cherbourg and bringing them to Southampton, and (b) to speed up the London-Paris service *via* Southampton and Le Havre by carrying passengers and mail by seaplane instead of by boat. Subsequently, it is proposed to operate a passenger and mail service between Southampton and the Channel Isles.

The services are to be carried out by aircraft designed and built by the Supermarine Aviation Works, Ltd., of Southampton. The scheme has the support of the London and South-Western Railway Company, who will actively co-operate in the matter of through bookings and railway connections, and the French railway companies concerned are to assist by providing suitable train connections for the through route to Paris.

The operating company will receive as subsidy 25 per cent of the gross earnings from passengers, goods and mail, plus a payment of £1 10s. per passenger and 1½d. per lb. of goods carried. These latter sums are half of the similar payments made on the London-Paris route.

This enterprise marks a very important step forward in the development of real commercial aviation, and everyone who is acquainted with the history of the Supermarine Aviation Works, Ltd., will hope that the venture will be as successful as it deserves to be, and will bring to them—as the constructors of the machine to be used—an adequate reward for their persistent faith in the value of marine aircraft for transport purposes.

French Aero Salon

December 15th next to January 2nd, 1923, is the date fixed for the next French Aero Salon—the eighth—to be held, as before, at the Grand Palais. The exact title has been changed to "Exposition Internationale de l'Aeronautique."

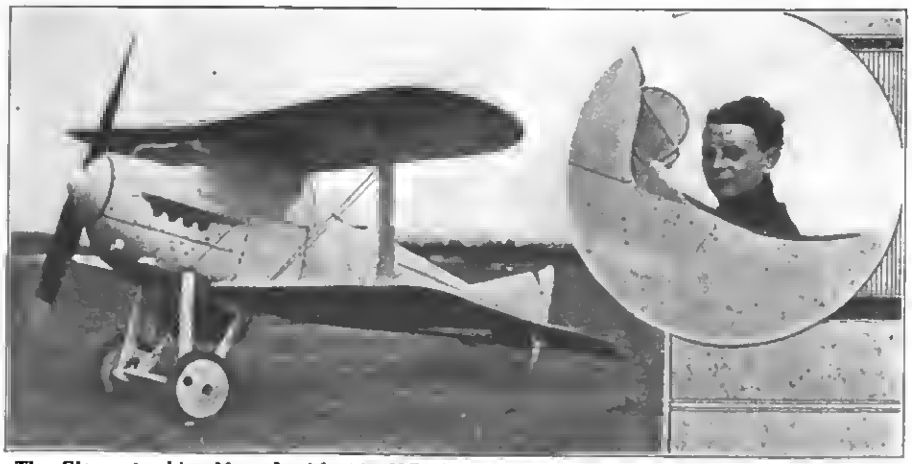
Italian Competition Entries

The results of the entries to the International Idro-Aviation Race of the Schneider Cup which closed on May 31st, according to the Italian National Aeronautical Federation, are as follows: *Italy*—5 machines—Two of the Macchi Firm, two of the Societa' Idrovolanti Alta Italia and one of the Pegua & Co. Among these three must be chosen. *France*—2 machines to be designated. *England*—2 machines to be designated.

The results of the entries for the Angelo Berardi Balloon Race are the following: *Italy*—8 ballons. *Belgium*—2 balloons.

The Berardi Balloon Race will take place June 4th in Milan.

The entries for the International Race for the Tyrrenean Cup and Grand Prize of Italy have been deferred until June 30th, 1922.



The Gloucestershire Mare I with 450 H.P. Napier Lion and Capt. James, who piloted the machine recently in England at 210 miles per hour

S. B. A. C. Officers

Mr. C. R. Fairey, M. B. E. (Chairman of the Fairey Aviation Co., Ltd.), has been elected Chairman of the Society of British Aircraft Constructors for the year 1922-23. Capt. P. D. Acland (Vickers, Ltd.) has been elected Vice-Chairman and Sqdn.-Comdr. James Bird (Supermarine Aviation Works, Ltd.) Hon. Treasurer.

Sir Henry White-Smith, C. B. E., the retiring Chairman, who has been Chairman of the Society since its formation in 1916, becomes Past-Chairman.

Twenty-Nine Days vs. Eight Days by Air

The Postmaster-General states that the air mail for Baghdad which was dispatched from London on May 18th reached Baghdad on May 26th. This was a particularly notable achievement, as the normal time occupied in transmission by the combined ordinary and air route is between 11 and 18 days, and by ordinary route all the way it is about 29 days.

Dutch Parcels Air-Post

The Postmaster-General announces that parcels addressed to any part of Holland may now be posted for conveyance from London to Rotterdam and Amsterdam by air and for express delivery by the Dutch Post Office. Parcels will be accepted at the Post Offices in London and in the larger provincial towns where air parcels for Paris and Brussels are already accepted. The scale of charges, inclusive of express delivery at the place of destination, will be as follows: For parcels weighing up to 3 lb., 4s.; 3-7 lb., 7s. 6d.; 7-11 lb., 10s. 6d. On parcels addressed "Poste Restante" the charges will be 6d. less.

There will be two dispatches by air each day. Parcels posted in London overnight, and, in the provinces, in time to be included in the night parcels mails to London, will normally be forwarded by air next morning and delivered in Rotterdam and Amsterdam the same evening, and in other parts of Holland by the second morning after posting. They should thus reach their destination two or three days earlier than if sent by the ordinary parcel service.

Another Polar Trip

Plans for Major Tryggve Gran's aeroplane flight across the North Pole from Spitzbergen are well under way. With his expedition he has been in Spitzbergen since May 29, and the company is now engaged in a survey of conditions in the neighborhood of Mourning Bay looking to the choice of a starting point.

With Major Gran are the relief pilot, Lieut. Richards, formerly of the British

Digitized by Google

Royal Air Force, who holds the record for the fasted flight from India to London; Thorlief Haug, a famous Norwegian skiing expert, and Jacob Tullin Thams, a navigator. They left Christiania May 20, without knowledge that Capt. Roald Amundson was then on his way to Nome to make ready for his projected flight across from Point Barrow, Alaska, in the opposite direction to that which they contemplate.

Aftenposten, the newspaper, is bearing the expense of the expedition, together with friends of Gran. Gran intentionally kept secret that he would try to cross the North Pole, to exclude competition.

Officially, the expedition's only determination is to find out whether aeroplanes can be useful to help seal hunters.

"Aeroplanes will quickly be able to find the seals' resting place and instruct hunting boats by wireless," Gran said before leaving Norway.

Major Tryggve Gran is one of the great adventurers of Europe. He comes of a noble Norwegian family and has been flying for the past twelve years. He was one of the first aviators to loop the loop, and in 1914, when a Lieutenant in the Norwegian Navy, made the first aeroplane flight across the North Sea.

One incident of this flight illustrates vividly the strides that have been made in aviation in recent years. In 1914 there was no such thing as an inclinometer, and knowing that he must fly through fog, Gran hung a lead plummet on a string before him in his cockpit. He had need of it, too, for in the course of his flight, and in the midst of the heaviest sort of a fog, he found the plummet hanging clear outside the cockpit. He was flying upside down!

Duirng the war Gran was a Major in the British Royal Force, commanding a bombing squadron in France. At the close of the war he became identified with the transatlantic projects, and went to Newfoundland as navigator of the Handley-Page Atlantic, commanded by Vice-Admiral Mark Kerr, which remained weatherbound at Harbor Grace while Hawker and Raynham adventured and failed, and while Alcock and Brown adventured and succeeded. The Atlantic was not ready for her attempt when the N-C boats got away from Trepassey to carry the American flag first across the sea by air.

Aviation is but one of the daring sports that Gran has espoused. Famous from boyhood for his skill on skis, he went with Scott to the Antartic in 1910 and was one of those who discovered the gallant explorer's body in 1912.

British Subsidy

In the course of a speech at the Annual Reunion of the Independent Air Force, in London, Captain Guest, Secretary of State for Air, stated briefly what the subsidy arrangement did for British constructors as follows:

(1) a direct payment of £3 per head per passenger that they carry; (2) machines on a hire purchase system at a total cost of three-quarters of their value; (3) change of machines at the companies' will; (4) meteorological services free; (5) use of aerodromes and sheds at a nominal charge; (6) Wireless and communication facilities gratis; (7) lighting services for night-flying purposes; and (8) benefits of Inspection and Research.

New Type Seaplane

The London correspondent of the New York *Herald* states that an aeroplane that according to its inventors promises to revolutionize flying soon will be submitted to practical test, according to information in aviation circles here. It is said to be unlike anything ever constructed before and is really a ship with wings. The utmost secrecy is maintained as to the details of its construction but it is said to mark the beginning of an aerial navy.

The plane is so constructed that it will not only float in calm waters, but it is claimed will be able to ride the roughest seas with the same security as an Atlantic liner. It is claimed that it will be equally airworthy. The hull is long, light and slender, without bulkheads. The elasticity of the hull which will make this possible is the outcome of many years' scientific research. The new machine will be a vast improvement on the present type of amphibians.

The experimental machine carries but seven persons, but designs for larger ones have already been made. The aeroplane will carry four or six engines and will be capable of traveling 100 miles an hour. It will be equipped with fog horns, anchors and riding lights. When not in the air it can travel on the water and thus accompany a battle fleet under all conditions.

Machines designed chiefly for commercial service will be able to cross the Atlantic Ocean in less than forty-eight hours, it is claimed, carrying a heavy load.

New Dutch Company

The aeroplane manufacturing industry in the Netherlands is being extended by the establishment at Rotterdam of a new concern, to be known as the National Aircraft Manufacturing Co. (N. V. Nationale Vliegtuig Industrie). This enterprise is to be financed by Dutch capital exclusively and is to have a new factory built specially for aeroplane production.—*Commerce Reports.*

The Fokker Aeroplane Works at Veere, the Netherlands, are now executing an order for 10 "F. 111" passenger aeroplanes, each equipped with a 350 h. p. Rolls-Royce engine. These follow 4 similar machines already constructed and forwarded to Berlin as the equipment for a new aeroplane service between Konigsberg and Moscow, which is being established by the Russo-German Navigation Co. It is announced in the Dutch press that the Soviet Government has already executed a mail carrying contract with the new company.

In the first three months of the current year, 18 flying machines valued at $84,248 have been exported from the Netherlands, as compared with 7 machines valued at $45,000 in the corresponding period of 1921. Of the 18 machines exported this year, 10 have gone to Russia, 2 to the Dutch East Indies and 4 to Germany, the destination of the other two not being known.—*Commerce Reports.*

The Vickers "Vulcan," with 350 H.P. Rolls Royce engine, to be used by the Instone Air Line on Trans-Channel Services

FOREIGN TECHNICAL DIGEST

The New Two-Seater Junkers Monoplane

The new two-seater Junkers monoplane is built to the designs of Dr. Junkers of Dessau. Owing to the activities of the Aeronautical Commission of Control—which prohibited the building of aircraft in Germany up to May 5th—the machine had to be built in another country. Experimental work on this particular type has occupied some 15 months, and has included tests to discover a satisfactory engine, experiments with wings arranged at the bottom of the fuselage as in previous Junkers' monoplanes, and finally with the present arrangement.

Like the previous Junkers, the machine is of all-metal structure, using the characteristic corrugated thin sheet duralumin covering. The wing, of thick section, built on multiple tubular spars, is of 11 metres span and is built in one piece. It is attached to the top of the fuselage, and its leading edge is cut out to accommodate the pilot's head—very much as in the case of the Fokker F.III type.

The wing is also recessed on its under surface to accommodate the petrol tank—which is fixed actually to the top of the fuselage behind the pilot, but is enclosed by the wing when this is in position.

Behind the pilot and under the wing is a passenger cabin, large enough to accommodate two passengers, with a side entrance on the starboard side.

The undercarriage consists of two axles, hinged to a sort of rudimentary keel below the breast of the fuselage, a pair of thrust tubes, lying behind the axle, but also approximately horizontal, and a nearly vertical telescopic strut, fitted with shock absorbers fixed to the axle ends and to the fuselage side.

The engine is one of the 50 h. p. 5 cylinder radial air-cooled Siemens Halske type, fitted to the nose of the fuselage, and very thoroughly cowled in. The direct driven air-screw carries on its boss a forward projecting cylindrical nose of some length, which is meant to protect the engine from contact with the ground in case of the machine standing on its nose.

The machine is designed for high-speed special transport work—such as newspaper work of the type associated with the name of Mr. Cobham in this country. Normally with full tanks it carries one passenger and a fair amount of baggage. With reduced fuel or with little or no baggage two passengers may be carried.

No precise details of dimensions, weight, or performance are yet available, but it is hoped that these may be available shortly.

New Safety Devices for Aeroplanes

As we note from time to time improvements in construction tending towards greater safety in flying, the conviction is reached that the aeroplane has not yet emerged from its experimental stage and that, through the inventive genius of man, the aeroplane will eventually reach such a state of perfection as to eliminate any further cause on the part of the skeptical-minded to characterize flying as hazardous.

In England there have recently been introduced two new devices for the aeroplane, both of them having to do with landings, admittedly one of the most difficult features of the art of flying. One of these devices is a shock-absorbing type of under-carriage and the other is a self-sealing gasoline tank designed to withstand the stresses set up by gun fire and in crashing.

The first-named invention, the oleo-pneumatic under-carriage, which has been designed by A. V. Roe & Co., of London, England, manufacturers of the Avro "Viper," should prove of great value in reducing the risk of landing on bad ground, and should also be of value for early training and night flying purposes. The *Aeroplane*, London, gives the following description of this invention:

"This gear consists of two main undercarriage legs which are coupled at the base to the axle, the axle again being hinged by two horizontal tubes to the bases of two steel tube Vees situated in line with the front legs. The main legs carr a shock-absorbing device which consists of a combination of oil and rubber, and it is so designed that about half the travel of the telescopic leg is taken on the oil before the rubber is picked up. The detail of the oil valve is "interdit." The rubber shock absorber is in the form of separate rings, so that no trouble is entailed in replacing any particular broken or frayed portion.

On the ground the weight of the machine is carried by a combination of oil and rubber, and as the machine takes off the plunger sinks to its lower limit of travel. On landing the oil takes the first shock, so that by the time the rubber comes into play there is sufficient oil beneath the plunger to prevent bouncing. Mr. Hinkler (pilot of the Avro "Viper" testing this undercarriage) by changing his usual faultless method of landing, has been demonstrating how this undercarriage defies even the most ham-handed of pilots, by deliberately flattening out at various heights ranging up to 20 feet from the ground and then "pancaking," and also by landing at 80 m. p. h. with very little flattening out, but it seemed that no amount of effort on his part could induce the machine to bounce. It pulls up in a remarkable short run, and owing to the wide track of the wheels (6 feet) it is possible to navigate on the ground at almost any sane speed.

From the demonstration, which one witnessed, it would seem that the Avro "Viper" so equipped could land and get out of the smallest and roughest of fields possible without any trouble. As a training machine it might tend to give newly fledged pilots too much confidence and make them careless when passing into less robust machines, but for fully trained pilots it would seem almost ideal and guard the machine against almost any type of cross-country flying accident."

The Crash-proof gasoline tank, above mentioned, styled the "Silvertown Anti-fire Self-Sealing Petrol Tank," which was awarded the first prize in the British Air Ministry competition, calling for fuel tanks that will withstand machine gun fire and crashes without leakage of contents, and which tanks were subjected to the most rigid and exacting tests, is described by the same publication as follows:

"The metal shell or tank proper consists of thin-gauge metal plate butt welded together and of such a form as to permit of a large increase of capacity before bringing any tensile stresses to bear on the metal, with the result that the seams successfully

The New Two-Seater Junkers Monoplane

Digitized by Google

withstand the stresses set up by gun fire and in crashing. This end is achieved by dishing inwards each side of the complete tank.

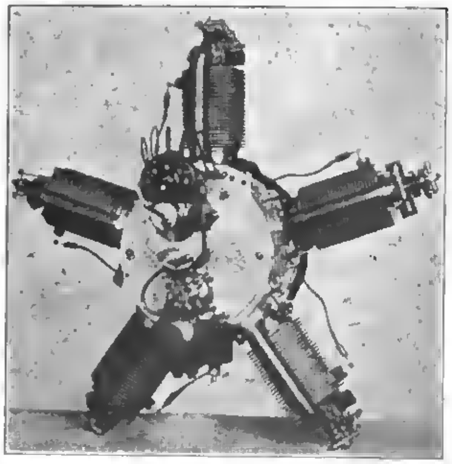
"The patent detachable cover is made of a high-grade rubber about a quarter of an inch thick, formed with an opening large enough to permit of the introduction of the shell. This opening is then closed with a closure piece of the same material suitably fastened in place, and it is claimed that this detachability renders the cover superior to any previous device. The cover can be manufactured and stored apart from the metal shell, and the latter can be removed from its cover and replaced at any time, without in any way causing damage to either.

"The judges appointed by the Air Council consider that the competition has resulted in the achievement of the objects for which it was instituted, and has produced a type of safety fuel tank which, although capable of improvement in several minor respects, is available for immediate introduction on Service and Civil aircraft, and which, for a slight increase of weight over and above that of the standard Service steel tank, gives almost complete immunity from fire, either in a crash or in action with enemy machines."

A New Low-Power German Radial Air-Cooled Aero Engine

LIMITED as Germany is to the use of engines not exceeding 60 h.p. for single-seater civilian aeroplanes, there is little doubt that the next two years, after which time the position is to be reconsidered, will see considerable progress made in the efficiency of German aircraft. The conditions imposed will force Germany, if she wishes to fly at all, to make such improvements in her aircraft as will enable it to do the work required with the limited power permitted. Thus, the restrictions may very easily turn out ultimately to be blessings in disguise. While other nations continue, in the main, to rely on power and more power, for increase in performance, load carrying or whatever purpose the particular design is being used for, Germany is prevented from taking this short cut, and will, of necessity, have to effect the necessary improvements by more efficient structural and aerodynamical design.

Whether in anticipation of a limit of 60 h.p. for single-seaters we cannot say, but the fact remains that, just about the time when the latest regulations came into force (May 5) the Siemens-Halske firm, of Siemensstadt, near Berlin, completed and tested a small radial air-cooled five-cylindered engine of approximately 60 h.p. In view of the fact that, up to the present, Germany has not produced many engines of this size, it may safely be assumed that the new Siemens-Halske engine is likely to become popular in Germany in the near future. The new engine has, we understand, been thoroughly tested, and is said to have given good results. We regret that no figures of weight, revolutions, consumption, etc., are available at the moment, but the following general description may not be without interest.



Front View

As will be seen from the accompanying photographs, the Siemens-Halske engine, with but five cylinders, is of very clean appearance, and should not, with suitable cowling, offer a great deal of air resistance. It is of the four-stroke type, with two valves to each cylinder. The bore is 100 mm., and the stroke 120 mm. The cylinders are of steel, with aluminium jackets having fins machined on them for cooling. The pistons are also aluminium, or aluminium alloy.

The aluminium crank-case is in two halves, and the flanged cylinder bases are bolted to it with four bolts each. As already mentioned, there are but two valves per cylinder. The inlet valve is operated by double rockers actuated by a push rod from the cam gear on the front of the engine. The exhaust valve is operated, also *via* push rods, by a single rocker arm, placed between the two rockers of the inlet valve. All rocker arms are carried in ball bearings. The valve stem guide of the exhaust valve is situated inside tubular T-piece, so that the exhaust gases escape through two openings. We believe that the manufacturers have designed a standard exhaust ring collector for this engine, so that from each exhaust valve cage, two short L-pipes run to the exhaust ring, which is placed *behind* the cylinders, and from which a single exhaust pipe projects upward in the typical German style. In the accompanying photographs this exhaust collector ring is not shown.

The rear portion of the crank-case contains the induction chamber, from which the various inlet valves are supplied through straight induction pipes bolted to the crank-case, and to the inlet valve cages. In the front portion of the crank-case are housed the cam discs and the thrust race. Needless to say, the camshaft, which is in two parts, runs in ball bearings. The high tension leads to the sparking plugs are housed in a ring on the front of the engine, and a single pipe carries all the leads from the magneto, which is mounted on a platform on the rear cover of the engine. The oil pump, which forces oil through the hollow crankshaft to the big ends, is also mounted on the rear cover of the crankcase. In its present form, the engine is provided with but one magneto, and there is only one sparking plug per cylinder, but we understand that, if desired, the manufacturers can supply the engine with complete dual ignition.

We hope that later some particulars relating to weight, r.p.m., fuel and oil consumption, compression ratio, etc., may become available, when we shall hope to publish them in AERIAL AGE.

ELEMENTARY AERONAUTICS and MODEL NOTES

Bird Flight Principles Compared to the Modern Aeroplanes

By F. F. Davis

THE study of bird flight resulted in men learning to fly, but have they not failed to use the great lesson of the bird's economy of power? And is the aeroplane, as we know it today, the best type of flying machine that can be built? To many, bird flight is a profound mystery, and some say it is impossible to learn much concerning it. Valuable information may be gained, however, by reading the works of the following: Etienne Jules Marey, Otto Lilienthal, F. W. Headley, James Bell Pettigrew, J. W. S. Rayleigh, Prof. S. P. Langley and many others. It will be found that some of these men have made long and careful studies of bird-flight and have used many instruments of their own invention for just that purpose.

By the use of electricity and photography, data has been gathered on the movement and power of birds' wings, close enough for practical purposes. It is found to be something like the following:

	Wing Span	*Supporting Area*	*Weight*	*Horse Power*
Condor	9-10 ft.	10 ft.	17 lb.	0.05
Turkey B'zard	6 ft.	5 ft.	5 lb.	0.015
Wild Goose .		2.7 ft.	9 lb.	0.026
Pigeon		0.7 ft.	1 lb.	0.012
Hu'ming Bird		0.3 in.	0.02 lb.	0.001

Enough Birds to Use One Horsepower

Wild Geese ..	346 lb.	101 sq. ft.	0.27 sq. ft. per lb.
Pigeons	83 lb.	58 sq. ft.	0.7 sq. ft. per lb.
Hu'ming Birds	15 lb.	26 sq. ft.	1.73 sq. ft. per lb.

By square feet is meant, *square feet of supporting surface.*

The best commercial monoplanes and biplanes early in 1922 did not carry in excess of twenty pounds per horsepower total weight, and the pay loads were near these figures:

Junker	3.54 lbs. per horsepower
Zeppelin Staaken ..	1.77 lbs. per horsepower
Bleriot Mammoth .	4.29 lbs. per horsepower
Fokker	4.77 lbs. per horsepower
Spad S-33	5.92 lbs. per horsepower

Aeroplane engines weigh from 1½ to more than 2 pounds per horsepower, and yet *two pounds of the muscles which move birds' wings give only a very small part of one horsepower.*

Aeroplane builders took the soaring or sailing bird for a model, but the flapping wing birds are far more economical in power expenditure. It is thought by many that in order to procure the same economy of power attributed to birds, it would be necessary to imitate every movement of the bird's wing, but in making machines to substitute the worth of the human hand (some far more complex than the flying machine we are thinking about), different movements are nearly always used to do the same work and it has been done faster and cheaper, too. Now the hand and arm perform more difficult and complicated movements than the wing of any bird.

For more than 25 years I have taken a deep interest in flying machines, having studied those that can fly to understand *why* they fly, and those that do not fly, to understand the reason for failure and to ascertain the good points in those failing to discover what features might be made use of. In 1919 I built a model flying machine on an entirely different principle from the aeroplane, which ran with a 2½ horsepower bicycle engine; it was geared back from the engine, but the engine was run up to its full speed. It is taken apart and is now in storage and I am anxious to build another as I now have more time, lighter materials and less to interfere with me while at work. I do not know of many men working on machines using this principle, but I am anxious to see some one build one well enough to show that it is far better than the aeroplane which has a propeller revolving cross-wise from the line of flight, giving a thrust of little more than three pounds per horsepower, with a great amount of wing surface that is a constant drag, that requires a specially prepared landing field and lands at a high rate of speed.

More people should study the flapping wing birds, swans, geese, ducks and many smaller birds, to appreciate the long distances they travel in a short time without depending on air currents.

It has been said that the reason birds fly with so little power is because they are so small, but study the figures given above comparing them with those stated in Prof. S. P. Langley's book "The Greatest Flying Creature" and this "reason" does not hold true.

The smaller the bird the greater the loss of power, and the more surface per pound required for its support. The swan weighs as much as 28 pounds and carries this weight far and fast on wings that are small for its weight. This is not done by any trick, but by a scientific principle of getting a fulcrum on the air, which is about 773 times lighter than water. The wing is a lever of the third class.

In making a machine to do the work of a hand or a wing or a leg, it is, of course, always better to use rotary motion rather than backward and forward motion in all parts that are suited to it and to use as few parts as will do the work in the right way with the least power.

It is important that our men of today use as a foundation the scientific knowledge that these pioneers have recorded in their books, and combine it with a knowledge of modern machinery and methods. It is not important to the world generally who hits upon the idea, but it is very important that some one does.

When the main principle of bird-flight is applied to transportation then civilization will take its next and greatest leap forward.

I wish to find others who are working along the same lines and would like to correspond with me.

Let each one do his own thinking and build his machine in his own way, but an exchange of ideas would be good, and if anyone is of the opinion that I may have stumbled on any little bit of knowledge in my reading that they have chanced to miss, let them write to me at 268 Willis Avenue, Bronx, New York City.

Hittle Tractor Hydro

THE Hittle tractor hydro record holder is of good design as its record of performance would indicate. Its record flight of 116 seconds has never been approached. The former record was only 29 seconds, making Mr. Hittle's flight all the more noteworthy.

Every possible method was used to cut down weight and resistance in every part of the model. This resulted in a total weight of only 1.75 ounce and an excellent glide of 8.75 to 1.

This model is a very stable flyer despite its light weight and large surface. It usually flies only 15 or 20 feet above the water but finishes up its flight with the motor practically all unwound.

Motor Base & Tail

A single white pine stick 5/16" deep and 45" long forms the motor-base. On the front the I. M. A. C. type of bearing for the propeller is bound and glued with a cellon base dope which is used on all joints. At the rear of the stick a piano wire hook for the rubber is attached.

The horizontal tail consists of a pie-shaped plane measuring 8" x 12" attached to the underside at the rear of the motor-base. The rudder, measuring 3½ to 3½ is attached at the rear of the rubber hook to the horizontal plane.

Wing

The wing is built of two white pine beams with ribs and tips of bamboo. A span of 43" and a chord of 5⅛" makes an area of 215 square inches. A slight dihedral is given the wing. The trailing edge is longer than the entering edge and the ribs are somewhat oblique in order to secure an even spacing.

The wing is fastened to the motor-base

Digitized by Google

with two bamboo clips which permit of adjustment. The wing is set at an angle of 4 degrees with the line of thrust. The wing tips are curved up slightly at the rear.

Floats

Two neat floats which take practically the whole weight of the machine are situated directly under the wing, just far enough to the rear of the center of gravity so that the model will not tip backwards. A single float of triangular section is just behind the propeller. The floats of bamboo construction are fastened to the frame with streamline bamboo struts.

The weight of the floats and struts complete with struts is only .23 oz.

Power Plant

The four-bladed propeller has a diameter of 10" with a theoretical pitch of 14". Two two-bladed propellers carved alike from 5/8" thick planks are joined together. The blades are fairly narrow, tapering almost to a point at the tips.

Five strands of 3/16" flat rubber drive the propeller at about 760 R. P. M. when in flight. The rubber was only given 1500 turns when it made its record flight and was wound less on the other trials, showing it to be capable of even longer flights.

The Lathrop Tractor Model

LATHROP'S tractor has an official record of 240 seconds, which is the best performance ever officially made by a rubber-driven model in this country. On the record flight the model disappeared from sight at the end of four minutes and, from what the observers reported, it seems logical that the machine went much longer. It was never found, although the surrounding territory was carefully searched.

There is nothing in the details of the machine which needs a lengthy dicussion here as the drawings clearly show the general construction principles. There was one of the standard type of cans used on the machine attached at the center of the motor-base. Three strands of 3/16" flat rubber were used, giving the ten inch diameter twelve-inch pitch propellers a 90 second motor run. This run was sufficient to make the model climb out of sight on the several flights of the model before it was lost on the longest of all time. The motor base was about 3/8" high.

The total weight of this wonderful model was 1 1/8 ounces complete. Though this was a wonderful model it is *not impossible* to make one that will beat it! Mr. Lathrop worked long and hard on models before receiving the reward but it is some reward—the longest officially timed duration flight of any model aeroplane ever flown anywhere in the whole world and, for all the witnesses of the flight know, it may still be going!

Cook 45 Riser

THE Cook 45 riser is of the twin propeller, pusher type. The two propellers are 12 inches in diameter, carved from blanks 3/4 inch thick. They are alike except that they are cut to turn in opposite directions, both revolving outward from the center on top. The blades have a width of 1" and are 1/16" thick. They are sandpapered, varnished, and finally balanced in order to ensure smooth running. Shafts of No. 16 piano wire are fastened in each and bent in a hook to receive the rubber.

The frame holding the rubber is made of two white pine strips 39" long and 3/8" x 1/8" in cross section. In the front they are tapered, glued and bound with silk thread. A piece of No. 16 piano wire is bent to form two hooks for the rubber, and is bound on. These strips are separated by two "X's" and a straight piece of bamboo 3/16" x 1/16" in cross section, bound on with thread. The brackets for the propellers are made from No. 12 wire flattened and drilled for the shafts, glued and bound to the strips. Small copper or brass washers are used to reduce the friction.

The front plane measures 14" x 3 1/2" and is made of 1/16" round bamboo. The three ribs are given the curvature of about 3/16" by bending the bamboo over a flame; any low flame such as a candle being satisfatory for this. The rear wing is surfaced on both top and bottom. The two wing spars are 3/16" x 1/16" set with the small edge up. They run the full length of the wing. The ribs are 1/16" x 1/8", double, one on top and one below for each complete rib. The edges are of 1/16" square bamboo. The wing is covered on top and bottom with tissue paper. After covering the paper is treated with banana oil to shrink it.

The landing gear is made of No. 16 piano wire bent to the shape shown in the drawings. The wheels are cork, carved with a razor blade. They have a small piece of brass tubing for the axle bushing. All joints are soldered. The rear skid is also made of piano wire bent to shape and soldered.

One and one-half ounces of strip rubber is divided between the two motors and is hung loosely between the two hooks. In emergency, if strip rubber is not obtainable, long narrow rubber bands looped together will do the work. In the front end the rubber should be attached to "S" hooks which permit it to be detached and wound up with a converted eggbeater. When winding the rubber up, it should be stretched to 2 1/2 or 3 times its normal length and then gradually shortened as it is wound. In this way many more winds can be safely given to the rubber.

Pond Indoor Model

THE Pond indoor model is a very slow and consistent flyer. At a contest in which this model made the flight of 170 seconds, the other two official flights were 160 and 164.6. making the average 30 seconds more than the former indoor world's record.

The builder of this model examined all of the available models around and selected parts on one and parts on another to copy for the present model. The best parts from each model were used. The resulting model won for the constructor a pair of racing ice skates.

Frame

The frame of the model is of balso wood. The front of the stick is strengthened by a protective coating of Ambroid, about 3/4 of an inch back from the nose. This prevents the soft balso wood from being chipped and broken at the part of the motor-base which is most likely to be broken.

The "cans" and tail-pieces are fastened to the motor-base by means of Ambroid cement. No experience of parts so fastened of coming loose was encountered.

The frame barely stands the strain put on it. Two strands of 1/8" flat rubber are used. This amount of rubber with a little slack was wound 1125 turns on the record flight.

Propeller

The 12" oar used on this machine is also of balsa wood. It is very thin. The shaft was secured in place by a drop of Ambroid on both sides of the propeller. The tips of the propeller are rounded only slightly, as shown in the drawing.

Wings

The wing is of bamboo construction. The ribs, beams and tips are fastened together by butt joints, with Ambroid cement. The wing is not very flexible in flight, but it is very flexible to handle. The incidence of the wing is adjustable to some extent by a fairly deep "can" at the rear of the wing.

The tail-plane at the rear of the motor-base has two degrees of negative-incidence, which, with the bend in the motor-base, gives the model a rapid climb. The paper on the wing and tail surfaces is not doped. The wing tips are rounded to prevent the twisting of the wing due to any uneven pulling of the paper.

The tissue paper was selected from about about 20 sheets for light weight.

Weights

The total weight of this machine is .19 (nineteen hundredths) of one ounce. The weight is distributed as follows: Rubber motor .06; motor-base .05; propeller .03; wing .05 of an ounce.

The total area of the wing is 62 square inches. The loading per square foot is $144/62 \times 19/100 = .441$ ounces per square foot. With such a large wing and so little rubber, the speed of the model is just about the rate a person normally walks.

The skid shown in the drawing in dotted lines is one suitable for using in case an R. O. G. machine is desired.

Pond Tractor Model

THE tractor distance model designed by Bertram Pond is of standard design, with the exception of the hollow

Digitized by Google

spar motor-base used. The record flight of 2,465 feet, accomplished on an unfavorable day, makes Mr. Pond's flight more noteworthy.

Even on a day when snow was on the ground a flight of 1,565 feet was made.

It is the light yet sturdy construction of the model which makes it independent of weather conditions. The total weight with six strands of 3/16" flat rubber is 1.47 oz. The glide ratio with the propeller off (but with the rubber on) is six to one.

Motor Base and Tail

A channeled spar with walls .025" to .028" thick with a cap of the same thickness glued on to it, forms the body of this machine. The stick is 3/16" x 7/16" in cross section and 33¼" long. (See detail drawing in the June 19th issue of AERIAL AGE). The channel was gouged out with hand tools and sandpapered to size, which was held to limits by the use of a micrometer. The cap was planed on a piece of plate glass for flatness, using a very thin cut. The cap was glued on with LePage's glue after the inside had been doped with banana oil.

The usual hook and bearing are fastened to the front and rear by Ambroid. Two 7/16" opening "cans" are used to prevent the motor-base from buckling.

The horizontal tail is formed of two bamboo strips with a split silk thread edging. The vertical member fits in the hollow of the spar, and it is of a shape to prevent warping.

The weight of the motor-base complete with fin is .35 ounce.

Wings

The wing is built up in the standard way with round tips to prevent warping. To counteract the efficiency loss accompanying a large dihedral or the loss of stability when the center of thrust is above the center of pressure (due to the depth of the motor spark) the front wing spar has a decided offset downwards sufficient to make the proper incidence and dihedral with both wing beams flat on the motor base. Also the center of pressure is raised without increasing the dihedral. The right side of the wing has more incidence than the left to take care of the torque of the propeller. The clips which hold the wing to the motor-base weigh .27 ounce.

Power Plant

The large 15" diameter 19½" pitch propeller is driven by six strands of rubber weighing .7 ounce. Propeller weight .15 ounce.

The rubber was given 825 winds on the record flight but will stand 1,200 as was proven later.

This model holds the unofficial Hand-Launched Distance and Duration Records with 6,300 feet and 522 seconds to its credit. It is a consistent flyer, having made 9 or 10 flights all over 1,500 feet. It usually climbs to a good altitude finishing up the flight in a very long but apparently steep glide, with the motor all unwound.

second will be counted by lowering the red flag, the getaway signal being the lowering of both red and white flags. If any contestant has difficulty in starting his motor, his assistant starter will not raise the red flag, but, when the chief starter raises the white warning flag, will raise a blue flag, which is a request for a deferred start. Deferred starts shall be granted without penalty, except that no plane will be allowed to start after a delay of one hour. Any plane having once started cannot receive another start; however, it may complete the race, though forced down, provided it can do so before 5 p. m.

4. THE FINISH:

The finishing time will be taken when each plane crosses the finish line between the marks indicating this line, after having completed the full course, approximately 240 miles.

5. WINNER:

The winner of first place in the race proper shall be the pilot who has completed the full course in the shortest elapsed time, and second place the second best time, etc., provided the pilot is not disqualified.

6. QUALIFICATIONS:

All pilots must hold an Aviator's license issued by the Federation Aeronautique Internationale and duly entered upon the Competitor's Register of the Aero Club of America.

7. RULES OF THE RACE:

(*a*) Pilots must hold a straight course after starting until they have gone the distance to be specified and marked.

(*b*) A plane overtaken must hold its altitude and a true course, in order that it may not in any way impede or interfere with a faster overtaking plane.

(*c*) A plane overtaking a slower plane shall never pass or attempt to pass between that plane and any pylon or captive balloon marking a turning point.

(*d*) Pilots shall pass all turning points in plain view of the observing officials stationed at each turning point and at an altitude of not over 500 feet.

(*e*) After crossing the finishing line, all planes shall continue on their course until they have attained the altitude of 2,000 feet, then they may turn and return to the Field, and land in that part of the Field assigned for landing and in so doing shall not cross the course or finish line.

Any contestant breaking any of the foregoing rules of the course, or subsequent ones which may be officially announced in writing, shall, upon recommendation of the judges, be disqualified.

8. PROTESTS:

No protest shall be considered unless presented in writing to the Contest Committee of the Detroit Aviation Society, Inc., within twenty-four hours after the finish of the race.

9. NUMBERS:

Each aeroplane shall have a number assigned to it by the Contest Committee, painted on the bottom surface of lower wing and on each side of the fuselage, clear of the wing, in characters as large as possible. It shall have no other numbering or lettering over 12 inches in height.

10. No contestant shall be permitted to "dope" the fuel with picric acid, ether, or similar highly explosive liquids. Benzol and similar anti-knock fuels may be used.

Event No. 5

Pulitzer Trophy, Saturday, September 16. Cash prizes: First prize, $1,200; second prize, $600; third prize, $200. Free-for-all race for high-speed aeroplanes.

1. CONDITIONS OF CONTEST:

(*a*) Factor of safety—Monoplanes, 7½ as loaded for start of race; biplanes, 6 as loaded for start of race.

(*b*) Air speed greater than 140 miles per hour, as loaded for start of race.

(*c*) Landing speed not to exceed 75 miles per hour in still air. (See foot note).

(*d*) Visibility and maneuverability (land and air) which, in opinion of Contest Committee, is not a menace to the other contestants or spectators.

2. DISTANCE:

Approximately 160 miles, four times around a closed course of 40 miles, starting at Selfridge Field, thence west to captive balloon, thence to Packard Field and return to Selfridge Field.

CONTRACTORS TO U. S. ARMY U. S. NAVY

Valentine & Company,
456 Fourth Ave., New York City

Gentlemen:

You will no doubt be interested to hear of the remarkable performance obtained by our new "Petrel," commercial three-seater, during tests recently.

Carrying a useful load of six hundred pounds the writer reached 7,000 feet in a climb of 22 minutes, with an initial climb rate of 510 feet per minute and established a high speed of 93 miles per hour, in clocked runs with and against the wind over a measured mile.

One of our stock models was exposed to the full violence of a Northern Climate during the past winter when it was left on the frozen St. Lawrence River for weeks at a time during testing and passenger carrying work.

Needless to say, however, the "Petrel," as well as all our products, is completely protected from the weather with Valspar and Valspar Enamels, to which we attribute to a large extent the highly gratifying results obtained.

Very truly yours,
HUFF DALAND AERO CORPORATION

George B. Post
Vice-Pres.

(*Continued from page* 408)

board of which General Shanks is president. Representations of the need of relief having been made by General Patrick, chief of the air service, it is hoped that some remedy will be recommended from that quarter requiring, of course, legislation. What this will be is not made known, but it is presumed that some plan will be adopted to place the air service personnel on a separate promotion list, after the manner of the medical corps, with possibly, promotion by length of service, although that is not essential, provided the advancement is made equitable as vacancies occur with the fair distribution of original air service officers to the field grades, from which they are now hopelessly excluded, or that the younger officers will be distributed on the present promotion list more equitably according to their actual length of service. This separation of air service officers from the promotion list would not, it is pointed out, interfere in the least with advancement in other hranches, excepting in so far as such officers would benefit from air service vacancies. It would be justified, it is urged, by the fact that the casualties are so prevalent in time of peace. It is expected that same important announcement of interest and importance to air service officers will be shortly forthcoming in the report of the board engaged in a study of the promotion list. The impression prevails that, if the War Department approves of any recommendation of this character, there will be no difficulty in obtaining the necessary helpful and corrective legislation from Congress. A striking illustration of the disadvantage under which the air service is placed is afforded by the fact that of the officers now eligible for promotion in the various grades there are no air service officers among the 24 lieutenant-colonels, only one (Foulois) among the 30 majors, only one (Houghton) among the 67 captains, and 24 among the 152 first lieutenants. It is interesting to note that practically all of the 24 officers who are eligible for advancement from first lieutenant to captain are those who were originally commissioned as ground officers or transferred into the air service from other arms in which they were initially commissioned, this being due to the fact that the bulk of all the original flying officers are still a considerable distance from the junior officers in the list of first lieutenants for whom there are vacancies in the grade of captain.—*Army and Navy Register.*
